recent observations,[19] when we were able to show by measurements of the respiratory exchange that during long-continued and moderately hard work an unduly high respiratory quotient might be found in the early stages of the work and that CO_2 production and hyperpnœa were at a maximum at this stage, though the respiratory quotient soon fell back to a value well within the normal range and the hyperpnœa diminished distinctly, the CO_2 production being definitely reduced below its initial value. Little further change occurred during the rest of the work, and it seemed therefore that the balance had been struck between lactic acid formation and its removal. The conception of this condition of balance has been further developed by A. V. Hill and his colleagues in what they call the "steady state" of muscular exercise, and it seems clear that not only the behaviour of the breathing, but also the limited degree of oxygen debt in this form of work can be in the main explained by the lactic acid theory of the development of muscular energy and the influence of increased CO_2 production and lactic acid formation on the hydrogen-ion concentration of the blood. The state of affairs differs in degree, but not in essential nature from that found in very severe muscular work; in the latter case the oxygen requirements, as distinct from the oxygen that can be absorbed and supplied to the muscles, are so excessive that the steady state cannot be attained.

Can we assume that the same argument can be applied in quite light muscular work—say, walking at three to four miles an hour—such as we are accustomed to do in everyday life? Haldane, Priestley, and I thought that in such cases the increase of stimulus to the respiratory centre was furnished by rise of CO_2 pressure alone. In those days we were under the impression that significant amounts of lactic acid were not formed so long as the work was quite light. At the slower rates of walking alveolar air analyses seemed to show a rise of alveolar CO_2 pressure which was sometimes at least adequate to account for the increased breathing as judged from experiments in which hyperpnœa was caused by breathing air to which CO_2 had been added, though this was not the case at the faster rates of walking. These results are, however, subject to a criticism that has been made by Krogh and Lindhard,[20] who have pointed out that alveolar air analyses made by the Haldane-Priestley method must afford figures for the CO_2 pressure which are unduly high owing to the unavoidable time occupied in making the essential forced expirations, and that though this error may be negligible when at rest it becomes significant when the CO_2 production is greatly increased by muscular work. This criticism is valid, though the authors probably over-estimated the magnitude of the error, and it will be referred to again in my second lecture.

It is possible, therefore, that Haldane and I were misled as to the degree to which the alveolar CO_2 pressure rises in light muscular work. This seems to be corroborated by A. V. Hill, Long, and Lupton,[10 21] for they have found a definite though slight increase of lactic acid in the blood whilst walking at three to four miles an hour. If this is so we should expect to find the true alteration in the alveolar CO_2 pressure insufficient to account for the increased breathing, since the change in hydrogen-ion concentration in the blood would be in part attributable to the effects of lactic acid. As we cannot place implicit confidence in analyses of the alveolar air alone, Mr. W. H. Owles and I have tried to confirm the results of the lactic acid analyses by direct estimations of the bicarbonate in the blood. After sitting at rest for an hour in the laboratory in the post-absorptive condition we withdrew a sample of blood from a vein in the arm and subsequently took another sample after we had walked for half an hour at a pace of three or three and a half miles an hour. Coagulation was prevented by adding oxalate and formation of lactic acid owing to glycolysis was hindered by the addition of sodium fluoride (Evans [22]). Both samples were then brought into equilibrium with air containing the same concentration of CO_2 at 38° C., the content of CO_2 combined in the blood as bicarbonate being then analysed. In two experiments we found the following results:—

Experiment.	Pace in miles per hour.	CO_2 pressure in mm. Hg with which blood was equilibrated.	C.cm. combined CO_2 per 100 c.cm. blood.
1	2·9	39·9	46·8 (B)
		40·0	47·2 (A)
2	3·4	38·9	45·4 (B)
		38·9	46·6 (A)

(B) = Before exercise. (A) = After exercise.

It will be seen that the exercise caused no fall in the CO_2 combining power of the blood; indeed, there seems to have been a slight increase. In view of this result I feel that I should like further information before committing myself to any definite view regarding the precise physicochemical changes which accompany the small increase of hydrogen-ion concentration in the blood during gentle exercise.

INFLUENCE OF FACTORS OTHER THAN HYDROGEN-ION CONCENTRATION.

The influence of the other two factors which must be taken into account during muscular work is less easy to define. The fact that as one ascends from sea level to a high altitude the breathing progressively increases and the alveolar CO_2 pressure progressively falls in the resting subject, effects which are known to be attributable to the decreased atmospheric oxygen pressure, seems to imply that we must regard the respiratory centre as being influenced all the time not only by the hydrogen-ion concentration in the arterial blood, but by the oxygen pressure as well. Provided that the arterial oxygen pressure can be kept up to its normal value during muscular work no difficulty will arise. Muscular work, however, leads to a great increase in the rate at which blood traverses the lungs and to a great reduction in the oxygen saturation of the venous blood entering the lungs, and as the distribution of oxygen in the different alveoli seems to be by no means even, some parts of the lung being at any moment less adequately ventilated than others, we may well believe that it will be difficult for the blood to get completely saturated with oxygen in its passage. If so, the effect of deficiency of oxygen will make itself felt on the respiratory centre and will exaggerate the hyperpnœa. Various observations show that we have to reckon with this effect. The benefit which has been recorded in the past as resulting from breathing oxygen during arduous work favours this view, and quantitative evidence has been furnished by the experiments of A. V. Hill, Long, and Lupton which have led them to agree that some degree of reduction of the oxygen saturation in the arterial blood during very severe work is responsible for prejudicial effects on the cerebral and cardiac system which set a limit to the amount of oxygen that can be absorbed when breathing air, a limit which can be readily passed when the subject breathes an oxygen-rich atmosphere. Deficiency in the saturation of the arterial blood with oxygen is therefore a real factor during severe work, but as yet there are insufficient data to indicate how hard the work must be for this deficiency to become significant, though this does seem to depend definitely on the physical fitness and training of the subject. Information is badly needed on this point, and it is particularly desirable that trials should be made with both trained and untrained subjects.

Deficiency of oxygen in the arterial blood will excite the respiratory centre and therefore increase the hyperpnœa, but the increased elimination of CO_2 in consequence of this will, by reducing the hydrogen-ion concentration of the blood, oppose this action, and a balance may therefore be struck with the hyperpnœa somewhat greater and the hydrogen-ion concentration somewhat lower than would otherwise be the case. As, however, increased rate of breathing caused by deficiency of oxygen tends to be accom-

panied by shallowness of respiration the ventilation of the lungs may be less effective than one would anticipate.

Difficult though it may be to define clearly the influence of deficiency of oxygen during muscular work our knowledge as to the possible effects on the respiration of changes of body temperature resulting from increased metabolism is even vaguer. An increase of body temperature in a normal resting person caused by exposure to an unduly high environmental temperature results in hyperpnœa in excess of what would be expected from the increased metabolism due to the high body temperature and a fall in alveolar CO_2 pressure, an effect that appears to be attributable to the fact that blood of abnormally high temperature reaches the respiratory centre. As is well known the body temperature, as judged by the readings of rectal thermometers, is increased by muscular work, but this fact need not necessarily imply that the temperature of the blood reaching the brain is above normal since the warm blood returning from the active parts of the body will be mixed in the heart with relatively cool blood coming back from the skin. If, as seems probable, the general regulation of heat production and heat loss so as to preserve the body temperature within due bounds is largely dependent on the effects exerted by slight changes of blood temperature on some centre in the brain, situated perhaps in the thalamic region, the fact that heat loss is increased by vascular changes in the skin and by sweating during muscular work may well be an indication that the temperature of the blood reaching the brain is higher than it is at rest. I have several times thought that I could detect some increase of the hyperpnœa during muscular work, as well as alterations of the alveolar CO_2 pressure after the work, which were attributable to a rise of temperature. In any case if the temperature factor does actually come into play its influence on the respiratory centre will resemble that of deficiency of oxygen, and like that it will tend to be opposed by the reduction of hydrogen-ion concentration which will result from the accentuation of the hyperpnœa.

THE NERVOUS FACTOR IN COÖRDINATION OF BREATHING WITH CHANGES IN BODILY ACTIVITY.

I have now devoted a great deal of time to a discussion of the influence on the breathing of changes in the arterial blood, and beyond casual reference to the respiratory centre I have apparently treated the part played by the nervous system itself with scant courtesy. In point of fact what I have really done is to assume the function of the nervous system. After all, when we are considering the coördination of the breathing with changes in bodily activity we are, if I may put it in that way, dealing with a reflex arc in which the efferent side has been in the main replaced by direct excitation of the effector nervous centre by chemical and physical stimuli reaching it through the blood stream. From that limited region of the brain that we call the respiratory centre the passage of efferent nervous impulses ensures the simultaneous and coördinated activity of all the respiratory muscles; it is impossible to conceive that this object could be attained if those muscles, distributed as they are over a wide region of the body, were individually and directly influenced by variations in the composition of the blood which reached them. Then what is the peculiar advantage of the direct physicochemical stimulus to the centre?

It is clear that if the breathing is to conform with changes in the metabolism the pace must somehow be set by the organs whose activity varies. Haldane and Priestley showed that the connecting link was apparently supplied by the direct influence of CO_2, the principle end-product of tissue metabolism, on the respiratory centre, transmission of the requisite stimulus taking place through the blood stream and not through afferent nerves. For CO_2 pressure in the blood we may now have substituted hydrogen-ion concentration, and we may have added to that such factors as deficiency of oxygen and even body temperature, and yet the fundamental conception holds good. Provided that alterations in the activity of the organs of the body impress on the blood stream certain types of chemical or physical change to which, as has been abundantly shown by experimental investigation, the respiratory centre is exquisitely sensitive, the quantity of air breathed must of necessity be correlated with the varying metabolism of the body. The coördination of the respiration is intimately bound up with the preservation of the hydrogen-ion concentration in the blood and tissues within certain narrow limits. As muscular work increases in severity lactic acid may play a more and more prominent part in raising the hydrogen-ion concentration, and the effects of deficiency of oxygen and rise of temperature may be superadded, but the very fact that increased breathing by eliminating CO_2 at a faster rate tends to reduce the hydrogen-ion concentration and so to counteract the influence of these factors ensures that a balance will be struck so long as the metabolism is within reasonable bounds, a balance which implies on the one hand that the hydrogen-ion concentration will not rise unduly, and on the other that the CO_2 produced by the active tissues will be effectively expelled—and appropriate expulsion of CO_2 means the maintenance of an adequate oxygen concentration in the lungs. The balance is only unattainable in the severer forms of exertion when the limits of respiratory and cardiac activity are reached while the muscles can still continue in functional activity in consequence of their capacity for the anaerobic development of energy.

While, however, we may recognise that the main stimulus to the respiratory centre is afforded by chemical or physical alterations in the blood with which it is supplied we must be careful not to forget that that centre is also played upon by impulses conveyed by nervous channels. I am referring neither to the reflex effects on the respiration which we encounter every time we cough, sneeze, or swallow, nor to the temporary alterations which result from certain forms of cutaneous stimulation or pain. What I have in mind is the constant influence exerted by afferent impulses passing up the vagus nerves from the lungs themselves. If these nerves are severed increase of the chemical stimulus still provokes an increase in the breathing, but the response of the respiratory centre is not as complete as it is normally, for though the breathing may increase in depth there may be but an inadequate change in rate. The actual conversion of the inspiratory phase of the breathing into the expiratory phase and vice versa as breath follows breath is largely determined by the passage of nervous impulses up the vagus nerves, which are initiated by inflation or deflation of the lungs, the moment at which this conversion shall become effective being dependent on the magnitude of the chemical stimulus at the time and the vigour with which the respiratory centre is acting in consequence.[18] The effect of these impulses is apparently to convert the natural rhythm of response of the respiratory centre to the existing chemical stimulus, with its uneconomical prolongation of the inspiratory and, perhaps, of the expiratory phases, into a rhythm which is not only more economical of energy when the breathing is quiet, but also permits of far greater latitude when the breathing is exaggerated, for the very fact that the vagal impulses induce the prompt conversion of the one phase of a breathing movement into the other means that when the stress comes it can be met by an increase of both depth and frequency of the breathing. This reflex influence exerted through the vagus nerves is accentuated by various factors, but from our present standpoint the most important of these is deficiency of oxygen. The hyperpnœa caused by breathing air containing an excess of CO_2 (simple effect of increased hydrogen-ion concentration) involves as a rule a far greater alteration in the depth of the breathing than in the rate, while mere depression of the oxygen concentration in the air breathed provokes an increase in the rate of the breathing rather than in the depth, and we can well

understand that maximum hyperpnœa is found under experimental conditions when the two stimuli are combined.

When we consider the means by which the different functions of the body are coördinated we are apt, according to our bias, to lay stress either on the part played by the nervous system or on some factor, chemical or physicochemical, transmitted through the blood stream. In part this depends on our point of view at the moment, but in favouring one aspect we are in danger of neglecting the other. If we reflect on the behaviour of the breathing under different conditions of rest and activity we cannot fail to appreciate, I think, the harmonious coöperation of the two methods. Each has its own peculiar sphere; there is no antagonism but only mutual assistance. The quantitative response of the respiratory centre which manifests itself in alterations of the volume of air entering and leaving the lungs is primarily to be attributed to the direct stimulus afforded by physicochemical changes in the arterial blood which reaches it, changes which are directly due to the varying metabolism of the different organs of the body. But this response can only attain its full value when its rhythm is influenced by impulses transmitted up the vagus nerves as the lungs vary in volume, while the coördinated activity of the inspiratory and expiratory muscles is ensured by their nervous connexion with the respiratory centre.

BELFAST CHILDREN'S HOSPITAL.—Mrs. Harold Barbour, wife of the Minister of Commerce in the Northern Parliament, has offered to subscribe £10,000 to the fund for the erection of a new children's hospital at Belfast. The new hospital will cost approximately £100,000, of which £25,000 is required for the out-patient department. It is proposed, however, to postpone the rebuilding of this department for a short time.

THE LATE DR. M. S. W. GUNNING.—The death is announced of Dr. Montague Shirley Wyatt Gunning, of Sheffield. Born in London in 1864, he was the son of Thomas Wyatt Gunning, barrister-at-law, and was educated at Christ Church, Oxford, and at University College Hospital. He took the Scottish triple diploma in 1888, and served for a time as ship's surgeon in the P. and O. On taking up general practice he worked at Montrose and later at Marborough, near Leicester, and from 1904 to 1909 he was assistant ophthalmic surgeon to the Leicester Infirmary. For the last ten years of his life he was county oculist to the Derbyshire Education Committee, and practised as an oculist at Sheffield. Dr. Gunning was an experienced entomologist, and was interested in many other branches of natural history, as well as in music. For some years before the war he held a captain's commission, serving with the 2nd North Midland Field Hospital. His wife died some months before him, and he leaves one son.

DIET AND ACCESSORY FOOD FACTORS

IN RELATION TO PREVENTION OF DISEASES OF THE TEETH.*

BY J. SIM WALLACE, M.D., D.Sc. GLASG., L.D.S. R.C.S. ENG.,

LECTURER ON PREVENTIVE DENTISTRY, KING'S COLLEGE HOSPITAL.

ALL are, I hope, familiar with the debt the dental profession owes to the late Prof. G. V. Black. It is, however, only his epoch-making "Investigation into the Chemical and Physical Characters of the Teeth" to which I would here refer, in which he showed that the molar teeth were more fully calcified than the incisors by about 2 per cent., though molars are from 6 to 30 times more subject to decay than the different incisors. The accuracy of this analysis was confirmed by Sir Charles Tomes in England, and Black concluded that—

"neither the density nor the percentage of lime salts, nor the strength, is in any degree a factor in predisposing the teeth to caries, or in hindering its inception or progress."

In another way Tomes further confirmed Black's findings. He analysed two sets of teeth to ascertain the percentage of salts.

"In one set the third molars were largely affected by caries, and incipient decay existed between many of the teeth; while in the other set, although much worn by attrition, the teeth were quite free from caries. The analysis gave 71·4 per cent. of salts in both cases."

Yet, even to the present day, theories are brought forward to explain why the teeth are not sufficiently or properly calcified, and these quite erroneous theories with regard to calcification have been used to explain the fundamental cause of dental caries! In view of the verified facts, could anything be a greater or more misleading waste of time?

STRUCTURE OF THE ENAMEL.

Let me now refer to the microscopic structure of the enamel. Leon Williams, in his unexcelled research on the pathology of enamel, showed that defects in structure "such as pits, grooves, fissures, pigmentations, granular and amorphous enamel, are common in the lower animals," whose teeth we know are practically free from caries. Moreover, with the aid of the finest lenses, and the highest magnification added to his own almost inimitable skill and care in the preparation of sections, he was unable to discover any difference or degenerative change in the microscopic structure of the enamel of the teeth of modern civilised man, as compared with that of his remote ancestors of thousands of years ago. He noted, too, that, in his judgment, "the more imperfectly formed teeth—so far as inherent structure was concerned—and he meant by that the proportion of lime salts which were contained or anything other than the grosser defects, such as were found in enamel, in a perfectly healthy mouth, would never decay, while in an unhealthy mouth—and by unhealthy he meant those conditions inimical to the preservation of the teeth—in such an unhealthy mouth the most perfectly formed tooth would never be able to resist decay." Of course, we dentists are all familiar with the obvious, we all frequently see hypoplastic teeth which have not decayed throughout a lifetime while we see the most perfect teeth gradually becoming ravaged by the disease. Indeed, in one and the same mouth we often see hypoplastic incisors persisting in not becoming carious, while the premolars and second molars, though perfectly formed and free from hypoplasia, succumb to decay.

CHEMICAL COMPOSITION OF THE ENAMEL.

Now let us consider the enamel from the chemical point of view. It has long been known that it contains

* A review of recent medical and dental research, delivered at the Academy of Medicine, New York, and at other cities in U.S.A. and Canada on a lecturing tour primarily organised by the California State Dental Association.

ittle or no organic matter. With the best technique hat science can devise, however, it is estimated that namel contains 1 per cent. of organic matter. Now what and where is this "organic matter" in the namel? According to Dr. Leon Williams and Mr. H. C. Mallison, it is to be found in the cuticle surrounding the enamel prism, and with regard to its hemical nature we are indebted to Prof. W. E. Geis for the information that it is a sclero-protein like Naismith's membrane, with which it is continuous before that membrane gets stripped from the surface of the enamel. According to Prof. Geis and Dr. Leon Williams this sclero-protein is possessed of considerable elasticity, and this might well be regarded as a sufficient explanation of its use. Nevertheless, his trace of organic matter intrigues some investigators. They assume that it possesses some mysterious vitality. Some even claim that the highly complex phenomena associated with immunity in the blood may be possessed by this 1 per cent. of organic matter which is firmly imbedded in the inorganic enamel. They appear to assume that antibodies presumably blessed with the power of exerting a specific restrictive or destructive action on the bacteria in the fermenting carbohydrates outside the tooth, are exuded from this sclero-protein! and this, notwithstanding the fact that in the earliest stages of caries it is just this part of the enamel, containing a trace of organic matter, which appears to facilitate the diffusion of acid through the enamel and allow of the decalcification of the interprismatic substance. The theory of immunity as exhibited in the blood with regard to bacteria is rational, no doubt, but the theory of immunity in enamel to the action of acid is not worthy of the dental profession.

THE DENTINE IN RELATION TO IMMUNITY.

We know that dentine is a hard substance chiefly of a calcareous nature, subject, like enamel, to decalcification by acid. We know definitely that it contains living organic matter in the dentinal tubules. But what does this undoubted organic matter do when the acids and bacteria associated with the carious process break through the enamel? Does it exhibit the phenomena associated with immunity? Most assuredly it does not. It is presumed, and no doubt correctly, that the translucent zone indicates a vital reaction, but it seems to have remarkably little effect in preventing the progress of decay. Indeed, we *know* that instead of resisting their onslaught the dentinal fibrils furnish invading bacteria with relatively favourable channels for the destruction of the dentine. If we know that the 28 per cent. of organic matter in the dentine does more harm than good with regard to resistance to the carious process, may it not be that the less we talk nonsense about the immunity of enamel the better?

THE RÔLE OF ACCESSORY FOOD FACTORS IN THE PREVENTION OF CARIES.

In my early investigations it became evident that there were several accessory food factors of great importance from the point of view of the prevention of caries, irregularities of the teeth, tartar, and pyorrhœa. Thus it seemed to me that the physical consistency of the food, when of such a nature that it required crushing and disintegration between the teeth, was often a factor helping in no small degree the cleansing of such parts of the enamel as were subjected to friction. But not all foods which required crushing were detergent in their effects. It was obvious that many prepared or denaturalised foods, such as biscuits, toffee, and chocolate, did not by any means leave the teeth clean. Rather was it found that foods such as these tended to cling about the teeth and remain in the crevices. In a general way it was found that the more detergent foods were of a fibrillar nature, and in the case of vegetables this fibrillar substance was usually the carbohydrate known as cellulose. Other adjuvants to the cleansing of the mouth, though not accessory food factors, were noted, such as mucus, which formed a slippery coating on the surface of the enamel, thus facilitating the removal of foods. Similarly, the solvent and flushing action of the saliva was taken into account, together with such accessory food factors as stimulated these secretions. Acids, pungent, aromatic, and stimulating principles were referred to, and the belief expressed that the constant withholding of these latter accessory food factors might give rise to atrophy of the salivary glands. It soon became evident that the accessory food factors to which I have referred were not only instrumental in maintaining oral hygiene, but that they ministered also to alimentary hygiene in a similar way. Note was specially made of the value of innutritious cellulose. These ideas have of late received considerable confirmation. Thus Dr. Percy R. Howe has shown that animals with intestinal derangement are quickly got into a healthy state by adding cellulose in the form of filter paper to their diet, and Dr. Wm. Cramer and Dr. A. N. Kingsbury have pointed out that in animals deprived of vitamin A the mucous glands atrophy and the alimentary canal becomes unhealthy. To be more explicit they say that—

> "in a normal animal the intestinal bacteria are restricted to the central lumen of the intestine," but lack of vitamin A deranges the alimentary canal, "the intestinal bacteria penetrate between the villi into the crypts of Lieberkühn and into the mucous glands of the cæcum, which they fill and where they proliferate."

In recent years many physiologists and biochemists have paid attention to one set of accessory factors sometimes referred to as stimulative in their mode of action. It is, however, extremely regrettable that they should have concentrated their attention so exclusively on these accessory food factors now known as vitamins, since, at least with regard to oral hygiene and the development of the jaw, the other accessory food factors are in practice very much more important, because it would appear that in civilised communities it but rarely happens that food as consumed is so thoroughly deprived of vitamins as to cause any trouble at all, or at least any specific disease. How little vitamin is required may be indicated by reference to the—

> "experiments of Rohmann, who has done much pioneer work in this field of research. This investigator claims to have been able to satisfy the nutritive requirements of mice with rations prepared by mixing a number of isolated and purified food components. His animals not only showed increase of body-weight from such diets, but were actually sufficiently well nourished to produce young."

It has since been claimed, however, that he failed to use sufficient care in insuring the purity of the components of his food mixture. But who is going to trouble to secure specially prepared vitamin-free foods, particularly considering that in an ordinary mixed meal the expense would be quite prohibitive?

A further indication with regard to how little vitamin is required may be gleaned from the classical experiments of Sir Gowland Hopkins. He found that in the case of rats, although they declined and died on a diet carefully purified (of vitamin), yet the addition of a very small daily allowance of milk, the total solids of which amounted to only 4 per cent. or less of the whole food eaten, induced normal and continual growth. As a sufficiency is better than excess, we might infer from experiments on rats that 96 per cent. of our foods ought to be vitamin free. However, if less than 4 per cent. of a food like milk containing vitamins *restores* an animal to health after having been completely deprived of these substances, is it not rational to conclude that even less is required to prevent animals losing their health?

It would really appear that, except perhaps in the case of scurvy, the rôle of vitamins is only of academic interest, and, as far as dentists are concerned, of no practical importance whatever. We never see, nor are we required to treat, patients in England suffering from beri-beri, xerophthalmia, rickets, or scurvy, nor are we called upon to give advice with regard to general arrested growth, as distinguished from growth

in the jaws, dependent upon the absence of vitamin A in the diet. Nevertheless, it may be well to review some recent speculations and experiments with regard to vitamins and the diseases of the teeth. This is perhaps particularly desirable at present, because in medical circles at least, misguided investigation has distracted attention from the other more important accessory food factors, and the old and fallacious belief that the lack of calcification or the bad quality of the tooth is the cause of the prevalence of caries has been revived.

THEORIES OF THE ÆTIOLOGY OF RICKETS.

Before referring specially to the teeth, it may be well to recall some of the fanciful ideas with regard to the causation of rickets which more recently have been abandoned. Not so many years ago the theory that rickets was a deficiency disease resulting from lack of fat-soluble A in the diet was widely accepted, even though Prof. Noel Paton and his colleagues in what is known as the "Glasgow school" showed that puppies could be healthily reared when vitamin A was carefully excluded from the diet, and, moreover, that rickets frequently appeared in children whose diet was relatively rich in this vitamin. It has, of course, been shown that rickets is not a deficiency disease resulting from lack of vitamin A, although it may now be contended that irradiated cholesterol, the so-called vitamin D, helps to prevent or cure the disease. Then it was shown that rickets was almost non-existent when the beneficent effect of sunlight was not withheld and as its curative effects on rickets were necessarily admitted, the hypothesis was put forward that the sunlight mobilised the vitamins, the absence of which had been presumed to be the cause of the trouble. In other words, the sunlight mobilised the little army of vitamins which was not there! It is now perhaps more generally believed that as far as a dietetic factor is concerned, the disease is the result of a positive cause, such as excess of unsuitable carbohydrates in the diet of young children, resulting in intestinal derangements. Nevertheless, the vitamin enthusiasts, presumably on account of the curative effect of cod-liver oil, now claim that the disease results from the absence of vitamin D.

When first we were introduced to the vitamin theories, we were told that these precious substances could only be manufactured by plants, and we were regaled with fairy tales about the green diatoms and algæ in the sea which manufactured these vitamins to be consumed and stored by little fish, but not used up, then consumed and stored by bigger fish but still not used up, and these in turn were devoured by the cod and the precious vitamins stored in their livers. Now it is admitted that all this fairy tale is hypothetical, as with the aid of ultra-violet light from the sun or elsewhere even human beings can manufacture this vitamin and pass it into the intestine through the bile duct. If, however, this be admitted, then it follows that vitamin D is not necessarily an accessory food factor at all; but that it is produced as the result of normal metabolism under hygienic conditions.

THE VITAMINS IN RELATION TO THE TEETH.

The assumptions made with regard to vitamin A and the causation of rickets were soon followed by similar assumptions with regard to hypoplasia in the teeth. It was pointed out, however, that with regard to the deciduous teeth, which become carious so generally, the number of hypoplastic teeth did not amount to 1 in 100, and thus that the astounding frequency of caries in the milk teeth could not be attributed to predisposition to the disease as a result of hypoplasia. Moreover, experiments were made with puppies which showed that the enamel of teeth which was hypoplastic when the first part of the crown was formed, became normal when fat-soluble vitamins were deliberately excluded from the diet after the hypoplastic part of the enamel had been formed, while, on the other hand, the enamel did not become hypoplastic even although there was n vitamin A in the diet. Since it has been shown tha lack of vitamin A is not the cause of rickets, I fanc similarly even enthusiastic vitaminists have abandone the vitamin A deficiency theory of dental hypoplasia

Naturally, I am not an opponent of theories whic claim that accessory food factors are of importance but a review of the facts brought forward in recen years indicates that except in so far as vitamins ma stimulate the glands of oral hygiene, they appear t be of no appreciable value in the prevention of denta caries or the irregularities of the teeth. As, however vitamins probably stimulate the glands of ora hygiene, and as it is just possible that indirectly th absence of vitamins may occasionally predispose t disease resulting in hypoplasia of the teeth, I woul like to suggest the way in which they possibly ac Let us first direct attention to vitamin A. This supposed to be the vitamin which promotes growth Its distribution in foods has recently been somewha confused by the admission that another so-calle vitamin, that is vitamin D, was not, as it were properly separated off when the experiments for th elucidation of the distribution of vitamin A wer made. Nevertheless, we may take it that it is to b found in animal fats and green vegetables. Pa ticularly we may say that the belief in its presenc in green vegetables is least likely to be erroneou Plants as well as animals require protection from th action of bacteria, and it has long been well know that sunlight has bactericidal activities. It may b presumed that sunlight produces some change in th composition of certain kinds of organic matter, an that the resulting substance has a deadly effect on th bacteria. Let us assume that food is eaten containin organic matter which may have thus been transforme by the action of ultra-violet rays, then these leth accompaniments of the food will not only tend destroy bacteria, but will also stimulate the glan in the alimentary canal which are provided for th control and removal of bacteria and obnoxio substances. Suppose, on the other hand, foods ha been eaten which have been completely purifie from these antibacterial substances produced by th action of sunlight, then the bacteria would have better opportunity of proliferating, and the glan for the preservation of alimentary hygiene would n have their normal stimulation. If, however, th bacteria in the intestine are not properly controlle they will produce toxins of various kinds whi interfere with normal metabolism and growt Similarly with vitamin D. This may be produced b irradiation from cholesterol and some other organ substances. Taken by the mouth this "vitamin would act much as does vitamin A. We kno however, that it is not always an accessory fo factor. As previously indicated, we recognise it ma be produced in the animal body by the action sunlight, and passed into the alimentary canal wi the bile. But the bile, as has long been known, h a controlling action on the bacteria and their produc and stimulates the alimentary canal to perform i normal functions in a proper way. Thus, the vitamins A and D are protective, inasmuch a directly or indirectly, they exert some antibacteri influence restraining the proliferation of the bacter and preventing them, as has been indicated, fro entrance into the glands of Lieberkühn and t mucous glands in the cæcum. In addition to t action of sunlight, exercise stimulates the prop functioning of the liver, and altogether we may s that the liver is a most important organ from t point of view of alimentary hygiene. According this theory it is not at all surprising to note th puppies could be reared without rickets when t puppies were given fresh air, exercise, and sunligh even though they were deprived of animal fa containing vitamin A and D. That cod-liver oil h a curative effect on rickets has long been known, a it can hardly excite surprise that a very useful dr in the treatment of rickets should have been found something extracted from the liver. It would simp

seem that the extract from the cod's liver supplied the intestine with the very substance which in a rickety child was absent from the biliary secretion as the result of improper feeding, lack of sunlight, exercise, and fresh air. It will thus be seen that it is really incorrect to speak about a "growth" vitamin, or an "antirachitic" vitamin, for growth is a primordial or inherent attribute of all living cells, at least until they become specialised in their functions, and it is not that the vitamin promotes growth, but rather that the absence of vitamins may allow toxic substances to retard or prevent it. Growth is almost completely controlled by hereditary causes and is affected in a remarkably small degree by dietetic vagaries, though partial starvation does affect it. Children follow their parents in size, not according to what they are given to eat but according to certain laws of heredity. If a deficient supply of vitamin A were to be regarded as the cause of the shocking prevalence of dental caries in England to-day, it would be difficult to explain why the stature of the English is greater now than it was a few hundred years ago. So, too, would it be difficult to explain why in New Zealand the children were specially well grown and heavy, while their teeth are considerably more ravaged with caries than are the teeth of English children in England. Similarly with the so-called antirachitic vitamin. The antitoxic or lethal substance, that is vitamin D, is not specifically antirachitic. The function of this substance is presumbly to control the bacteria and their products in the intestine, as these, if uncontrolled, may predispose to or give rise to rickets and other diseases.

An interesting corroboration of this view is to be found in certain dental considerations. Dr. H. Waller has brought forward conclusive evidence that oral sepsis produces such a change in mother's milk, that a child deriving its milk from its own mother fails to grow and put on weight so long as the oral sepsis continues. When, however, the oral sepsis is put right, generally simply by the extraction of all the teeth, and without change of diet, the child begins to thrive and put on weight. Thus it is evident that ill-health, loss of weight, and absence of growth in the infant resulted from toxins and not from lack of any vitamins in the mother's diet.

Now let me refer briefly to vitamin B. Beri-beri is the disease which is commonly said to result from the absence of this vitamin in the diet. It has been noted that in those countries where this disease is prevalent, the teeth are relatively excellent. This I had the opportunity of verifying to some extent during a voyage to the East last year. Now, if beri-beri results simply from a deficiency of vitamin B, as many vitamin enthusiasts might like us to believe, its epidemic nature would be difficult to explain. On the other hand, if we admit that Nature has made a wise provision in putting some substances of an anti-bacterial nature into the covering of the grain, we see how polished rice, having this protective coating removed, may allow the bacteria or virus which causes an epidemic of beri-beri to proliferate on the unprotected grain.[1] This would explain why beri-beri might break out in epidemic form in a district where the bacteria or virus causing the disease were present, whereas in countries in which white rice and other decorticated grains were almost exclusively eaten, the disease would not occur if the active cause were not present.

With regard to vitamin C I have no intention of saying anything against it, although as far as dental caries is concerned it may be of as little consequence as any other vitamin. This vitamin is known to be rather easily destroyed by cooking, and one of the principles of dietetics which I claimed to be of value many years ago was that the dietary should contain some uncooked food. If the assumption that vitamin C is necessary in the dietary be correct, then the desirability of uncooked fruit and vegetables will have all the better chance of coming into vogue. The limitation of the conception of accessory food factors to vitamins is, as already indicated, very regrettable, since the other accessory food factors are of much greater practical value, especially with regard to the prevention of the diseases of the teeth. Moreover, when the other accessory food factors which are destroyed by cookery and the ultra refinement of food are sufficiently retained in the diet, it may be seen that the accessory food factors known as vitamins are amply provided for.

Here, however, it should be said that cooking was probably primarily beneficial in that it destroyed or removed an excess of lethal substances or vitamins which were useful to the plants but injurious to the animals that tried to consume them. Of course, like many other good things, cookery and the refinement of food can be carried too far, and the presentation of food to children in a chemically pure form—e.g., sugar, and concoctions made with it, may, and does, give rise to disastrous results.

DIETARY OF CHILDREN IN RELATION TO THE PREVENTION OF CARIES.

Let me now give you an illustration of the dietary for children advocated many years ago for the prevention of dental caries. It may be regarded as the prototype of numerous leaflets which have since been issued in England. It reads as follows:—

Important Short Rules for the Prevention of Decay in Teeth and Associated Diseases.

1. During the first two and a half years of life *all* starchy *or sugary food* (except milk) *should be given in a firm or fibrous form*, so as to stimulate mastication and insalivation, and thus promote the healthy growth of the jaws and the regular arrangement of the teeth. Bread, rusks, or any other farinaceous foods should never be added to or soaked in milk. Bread with crust (and butter), toasted bread (and butter), should form a considerable part of the solid part of the meals habitually given to children of this age. As the infant passes from the milk diet to the more solid diet the milk should be more and more diluted with water. During this period also the solid food should be eaten first and the milk and water taken after.

2. *After the age of two and a half years children should always have a considerable amount of the farinaceous food in a form which will stimulate a pleasurable amount of efficient mastication.* The albuminous part of their diet should also be presented in a form which will encourage mastication—e.g., boiled fish, meat, and later, bacon. Milk or milk substitutes should only be allowed in small amounts.

3. The meals should be *arranged* in such a way that if soft, starchy, or sugary food has been eaten, the mouth and teeth will be cleansed by food of a detergent nature taken immediately after. Thus, therefore, when sweets of any kind—e.g., milk puddings, jam rolls, cake, sweet biscuits, bread and marmalade, or jam are eaten, fresh fruit should be taken afterwards.

4. *Three meals daily are to be preferred to any greater number*, as the longer the interval the more hygienic is the state of the mouth and stomach and, therefore, the more perfectly adapted for the reception of a further meal. *Sweets, chocolate, or biscuit and milk should never be eaten between meals, or before going to bed.*

Then followed two lists of foods indicating those which were liable to induce dental caries and those which tended to prevent it.

Not Cleansing and Liable to induce Dental Caries.—Farinaceous and sugary foods in general, without fibrous element. Examples: Sweet biscuits and cake, bread and marmalade, bread and jam, new bread without crust, bread soaked in milk, milk puddings, porridge and milk, preserved fruit, chocolate and sweets of all kinds, honey. Liquids: Cocoa and chocolate.

Cleansing and Preventive of Dental Caries.—Fibrous foods generally. Examples: Fish, meat, bacon, poultry, uncooked vegetables, lettuce, cress, radish, celery. Cooked vegetables are, as a rule, cleansing, but in a less degree than uncooked vegetables. Stale bread with crust, toasted bread of all kinds, twice baked bread, pulled bread and cheese. Savouries. Fresh fruits, especially those requiring mastication—e.g., apples. Fatty foods—e.g., butter, margarine. Liquids: Tea, coffee, water; also soups and beef tea.[2]

[1] For a full explanation of this, or a similar theory, see Marine Hygiene and Sanitation, by Gilbert E. Brooke, Chief Health Officer, Straits Settlement Medical Department.

[2] Selected for use in the Clinic of the Preventive Dentistry and Oral Hygiene Department, Harvard Dental School.

It will be seen that these rules and the detergent types of food indicated provide amply for all the vitamins that are required. When writing these rules I had in mind the fact that the prevention of dental caries should not be considered an entity in itself, and consequently this dietary was intended to make provision for the prevention of tartar, pyorrhœa, the irregularities of the teeth, and indeed of all other diseases, so far as this was possible as a result of dietary reform. You will note that not only was the accessory food factor in the nature of the physical consistency of the food specially provided for, together with the stimulants required for the glands of oral hygiene, but also that the sequence of the articles of diet in the meal was so arranged that the mouth would be left in a hygienic state—i.e., the detergent foods come last. The non-recognition of these points is the chief error in most diets recommended for children, if indeed we overlook the harm that is often done by the unbridled recommendation of the articles of diet in the non-detergent list.

Suppose, however, that a dietary were suggested, as it frequently is, based on the presumed value of vitamins, all of which have no value in encouraging mastication, what use would it be from the point of view of the prevention of decay or the irregularities of the teeth? What value would it be from the point of view of a balanced diet? What value would it even be from the point of view of nutrition and energy? How far the attempt to construct a dietary on a vitaminic basis has been carried for the prevention of diseases which hardly ever exist in civilised countries, may be indicated by a recommendation recently given in the editorial columns of a medical paper. The subject under consideration was the prevention of dental caries, yet the author of the article maintained that bacon should be omitted from the dietary! There are few foods so excellently adapted for the stimulation of mastication and oral hygiene as bacon, and few are equal to it from the point of view of nourishment, energy, and heat production. Moreover, flavour or tastiness in food is not to be despised. Another recommendation showing the folly of basing a dietary for children on vitaminic considerations is to be seen in the advocacy of milk and cereal food. This amounts to little more than prolonging the age of pap feeding and the continuity of the shocking prevalence of the diseases of the teeth. The children in races like the Maori in New Zealand, the Eskimo in the Far North, and the Aboriginals in Australia are never given cow's milk, and cereals, if eaten at all, form but a negligible part of their dietary, yet their teeth are unexcelled by any other race in the world with regard to freedom from caries. It is thoroughly well recognised that where the land flows with milk and honey, there you have caries rampant in the classes which get these foods most, notwithstanding their vitamin content. Surely by this time dieticians might know that the hygiene of the mouth was not ministered to by milk, bread soaked in milk, milk puddings, and biscuits and milk. These and other like foods are examples of what should not be recommended by anyone having the slightest regard for the teeth or oral hygiene. It is lamentable to think that medical men are apparently still oblivious of the fact that a child of 2½ years is almost invariably blessed with a full set of most excellent and efficient teeth, and that the craze for vitamins makes them imagine that a milk diet mixed with other highly fermentable carbohydrates can be plastered about the crevices of the teeth without leading to the destruction of the natural denture. Even although the cereal were taken with the husk, say, in the form of brown bread, this as has been shown, ferments when masticated and mixed with saliva as rapidly as white bread, and the difference in its tendency to lodge about the teeth is not very notably less. If food values were to be adjusted according to the narrow theories of vitamin enthusiasts who base their beliefs on animal experiments, why should they not boldly advocate a diet of green grass and dandelions?—especially for nursing mothers.

Surely it should be recognised that different speci of animals have different requirements with regard food and feeding, apart from its vitamin content Scraped carrots and mushy spinach may be all rig for rats, in order to supply vitamins which have bee carefully excluded from their diet. But such foo will not stimulate mastication in young children. other ways, too, they may be quite unsatisfactor Thus the amount of fat and protein and nutriti generally is disproportionately small compared wi the innutritious cellulose, and the digestibility of t mixture leaves much to be desired. Perhaps one the unexplored problems is the most desirable for of cellulose. There are reasons for thinking that t cellulose in coarse brown bread, for example, is n always the most suitable. Whether this is due to t kind of vitamin present, or some other cause, does n seem to have been investigated, and although advocating dietary reform I have for more than quarter of a century maintained that we should t to preserve the essential similarity of the environme and dietary to that which obtained during t evolution of the species, yet it must be remember that cereal foods are somewhat artificial products civilisation, even though the whole grain is inc porated in the completed article of diet. I am afra however, the question cannot be settled by experimer on rats, dogs, guinea-pigs, and other animals.

AMOUNT OF VITAMINS REQUIRED.

Let us return again to a consideration of the amou which is required. We have noted that less than 4 p cent. of foods containing vitamins is all that necessary to restore an animal to health even af previous depletion of vitamins in the food. Nev theless, it seems to me that a considerable range possible. However, when we recognise that vitam are probably substances of a lethal nature, we mu observe that there is a possibility of doing harm advocating a dietary containing an excess of the substances. One might bring forward much evide which would suggest that an excessive vitamin inta was frequently more harmful than beneficial. Th many people are not able to eat much fruit or uncook green vegetables without feeling harmful effec Many, too, are liable to be upset by milk, crea animal fats, and coarse brown bread, notwithstandi the general truth that these foods contain nouri- ment in a very good assimilable form, and physician of experience would venture to treat a ch suffering from rickets by at once administering la doses of cod-liver oil. It might be fair to say th the amount required is just enough to prevent t glands of oral and alimentary hygiene from becom atrophied or otherwise hindered from perform their proper functions. Since vitamins are pres in small amounts in many animal tissues, it is possi that they may be stored and presumably transfer to any tissue which might be liable to be invaded bacteria. On the other hand, as they are found the fæces it is presumable that when present in unc amounts they are kept out of the system. They only partially absorbed and the bulk may thus passed out together with the bacteria whose growth th may have restrained. Our attention is specially dra to the fact that it is not desirable to have an exc of vitamin D, since where or when ultra-violet li is abundant the skin is permanently pigmented, a even where sunlight is not abundant, provision made for controlling the amount of this vitamin temporarily tanning the skin. Nor have we any evidence that large amounts of vitamin A are of slightest use in the prevention of caries. In relativ wealthy countries, especially among the well-to-, the animal part of children's diet consists largely milk, eggs, and butter, yet their teeth are a disgr to civilisation.

If these views may be taken as an explanation m consistent with the facts than is generally given, see that the word "vitamin" is even more ob tionable than it has already been shown to Vitality is inherent in all living tissues, and vitam

e not required to impart it. They only help to event bacteria and their toxins from interfering ith vitality. Thus, instead of comparing vitamins the electric spark in a motor engine, we should ther call them "mortamins," and to see in them the tivities which might be attributed to Nature's anti-cterial or, indirectly, germicidal drugs. Should this the correct explanation and if research workers not recognise it, they may heap up confusion even ore than they have already done in their search r an explanation of the activities of vitamins.

It should always be observed that caries originates tirely from conditions external to the tooth. The icroscopic structure below the surface of the amel has nothing whatever to do with its cause, ly the external form and relations of the tooth can fect this. And if any hope for further profitable search with regard to vitamins and dental caries is be made, this must be recognised. There are three ays in which vitamins, or rather "mortamins," ight help in the prevention of caries: (1) They ight, and probably do, stimulate the proper func-oning of the glands of oral hygiene. (2) They ight inhibit the proliferation and activities of the id-forming bacteria associated with the disease.) We know that nitrate of silver may stain and rmeate the enamel, more especially where it is fective, and that this has an inhibitive effect the progress of caries. It is just possible that mortamins" might act in a similar way. We need t consider the hypothesis that vitamins, lymph, or tibodies coming via the pulp are the factors quired to harden or to secure immunity of the amel to caries, since teeth with extirpated pulp ay and generally do show an equally "vital" or adly resistance to the disease.

Let me now conclude by giving a more concrete ustration in practical dietetics of some of the regoing observations. Let us analyse a simple eal, breakfast, for example. The most generally mitted dietetic principle is that man is a mixed eder. He does not, neither does he care to, live bread alone. But bread is a staple article of diet d almost invariably forms part of the breakfast eal. Now, in England, at least, there has been much ntroversy with regard to the relative value of white of brown bread. Particularly in recent years it has en claimed that white bread was devitalised, vitaminised, and in various other ways rendered eless or harmful. It was condemned most frequently cause it did not contain everything. But, as indi-ed, man is a mixed feeder and it would be most desirable to be able to produce a bread or food d live entirely upon it. As bread is not a complete d, and let us hope it never will be, we have to nsider not only what foods go best with it to make complete meal, but also what kind of bread goes st with the other necessary accompaniments. course, we know that bread is deficient in fat, and centuries at least the usual addition to the bread compensate for this was butter. In addition to s, a light breakfast would include something in the ture of café au lait. Thus the 4 per cent. of aminic food would be well provided or. But in gland this would be considered a rather poor akfast. The most usual addition to the light akfast referred to is an egg. The yolk contains ich supply of vitamins. Still more then it is not essary to have a bread containing much or even vitamin. Two eggs are generally considered eggy. May not this be due to excess of vitamin? rasher of bacon in addition to the egg is most erally welcome. This does not increase the amount vitamin. These additions give rather better ance to the meal, and provide a form of protein higher biological value than the protein contained the bread. When an egg-and-bacon breakfast is en, it is generally considered desirable to have the te bread toasted and the butter which would mpany the simple bread-and-butter breakfast is erally omitted. It is perhaps significant that n has chosen or prefers to eat toasted white bread with bacon and egg. Instinctively, he does not want to upset his liver with too much egg, nor to have a good meal spoiled with an excess of vitamins.

Of course, there are many other points to be considered. White bread appears to keep better than brown bread. It certainly toasts better, and with bacon it tastes better. While toasted bread stimulates mastication, this can hardly be said with regard to an egg. A rasher of bacon, however, together with the toast supplies most excellently all that is necessary from this point of view.

A good meal may easily be changed into a bad one, and this is often still done by finishing it off with bread and marmalade, jam, or honey. There is amply sufficient in the egg-and-bacon breakfast without this tooth-destroying addition, but if a special finish is required apart from taking the coffee last, the hygienic termination can easily be got from fresh, firm, fibrillar fruit full of fragrant flavour.

PYREXIA INDUCED BY INTRAVENOUS PROTEIN THERAPY IN GENERAL PARALYSIS.

BY J. M. MACKENZIE, M.B., CH.B. GLASG.,
DEPUTY MEDICAL SUPERINTENDENT, RUBERY HILL MENTAL HOSPITAL, BIRMINGHAM.

FOR many years past non-specific protein therapy has had its place in the field of medicine. The mode of action of these foreign proteins still remains obscure, but one thing they have in common—namely, the capacity to produce pyrexia if given in appropriate dosage.

Of recent years the malarial treatment of general paralysis has been attracting attention, and results have been recorded which would seem to justify its use. As a result of the experience obtained by the study of a series of cases treated by malaria and reported jointly with Dr. H. E. Brown, of this service, in the Board of Control's annual report for 1925, it was decided to treat a further series by means of what one might term "artificial malaria," the pyrexia being induced by intravenous injections of T.A.B. vaccine.

The work is not yet completed, only two cases out of a total of 13 commenced having finished the course of treatment decided upon and described below, but the results obtained, as stated in a brief communication in the Board of Control's annual report for 1925, seem to warrant a further note.

Kunde, Hall, and Gerty [1] report a series of 12 cases treated by 13 injections on alternate days of mixed typhoid vaccine, giving an average temperature on the chart shown of 103·2° F. The dosage used increased gradually from 200 to 500 millions.

The material used has been the stock vaccine prepared by Burroughs and Wellcome, containing 1000 million *B. typhosus* and 750 million each *B. paratyphosus* A and *paratyphosus* B per c.cm.

The course decided upon here is as follows:—

1. A series of ten daily intravenous injections of T.A.B. vaccine increasing in dosage from 300 millions to 6000 millions.
2. A series of four intravenous injections at weekly intervals of 0·45 g. N.A.B.
3. A series of ten vaccine injections daily with a dosage increasing from 1500 millions to 25,000 millions.
4. An exactly similar series of N.A.B. injections to (2).
5 and 6. A repetition of (3) and (4).

The interval between each of the above series of injections averages four weeks, and complete serological examination of blood and cerebro-spinal fluid is carried out between the stages.

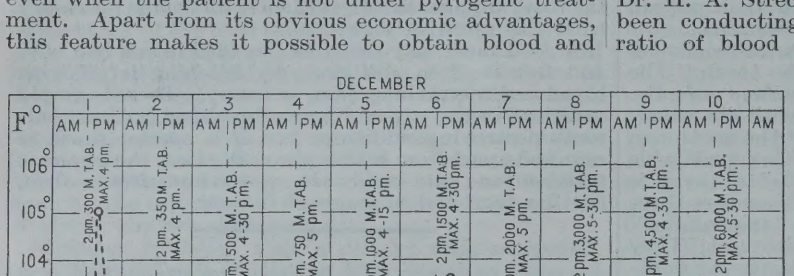
Results.

Temperatures up to 106° F. have been registered (see chart), and the average is well up to the standard obtained in the pyrexia of malaria. The

[1] Jour. Amer. Med. Assoc., Oct. 23rd, 1926.

rigors are severe, vomiting and diarrhœa occur frequently, but no permanent ill-effect has been noted in spite of the massive doses used. The occurrence of protein cachexia mentioned by Petersen [2] has not been observed.

Perhaps the most striking immediate result of the vaccine injections is to be seen in cases of excited general paralysis. The extreme motor restlessness is quickly controlled, and so far seems not to return even when the patient is not under pyrogenic treatment. Apart from its obvious economic advantages, this feature makes it possible to obtain blood and cerebro-spinal fluid for examination with the minimum of difficulty whenever desired.



Focal reactions have been noted in several cases, notably in one man who developed apical abscesses related to some dental stumps, and remained extremely restless and violent until these were extracted. This case serves to emphasise the importance of dealing with such obvious sources of irritation and toxin production before undertaking anything further.

One patient developed well-marked herpes in the region of distribution of the lacrymal branch of the ophthalmic division of the trigeminal nerve, which cleared up, leaving slight scarring behind. This raises the question of the possibility of a focal reaction in the Gasserian ganglion. Most of the cases developed at one time or another ordinary herpes febrilis in the circumoral region.

It is not yet time to give figures, as treatment of this series was commenced only in December, 1925, and is as yet by no means complete, but in general, certain beneficial results have been noted, as follows: Restless and excited paretics have become quiet and easily managed, and considerable physical and mental improvement has occurred in those cases which were not too far advanced in the disease at the commencement of treatment. The above series represent the ordinary general paralytic admitted to this mental hospital, not specially selected cases, and it is an unfortunate fact that one does not often see really early general paralysis in these institutions. As far as could be ascertained the average duration of the disease from the earliest symptoms before the commencement of treatment in the above series was about 15 months.

Several men, formerly slovenly in dress, careless in habits, and quarrelsome in nature are now clean, tidy, and helping in the routine ward work. Ten cases are at present in one small ward with, so far, complete immunity from the crop of minor accidents and quarrels that in the ordinary way one would expect to result from the misdirected activities of that number of general paralytics living together.

No constant change has taken place in the Wassermann reaction in either blood or cerebro-spinal fluid. Negative results have been returned on occasion, only to be succeeded by a positive finding later. The gold-sol test and the globulin and cell content also show no constant alteration. In connexion with these cases, Dr. H. A. Strecker of the research laboratory, has been conducting an investigation into the bromine ratio of blood serum and cerebro-spinal fluid, the result of which it is intended to communicate later.

Advantages and Disadvantages of the Treatment.

The *advantages* of this form of fever production, as compared with that obtained by malaria, appear to be as follows:—

1. A regularly recurring high degree of fever can be produced by appropriate dosage, similar to that produced by malaria (vide chart).

2. A living organism is not introduced.

3. The material is standardised and easily obtained; it is possible to regulate the amount given accurately.

4. The disadvantages connected with the use of mosquitoes are obviated—namely, special transport facilities and storage apparatus—as well as anti-mosquito rooms and nets, thus enabling the treatment to be carried out even in summer.

5. There is no incubation period and there is no possibility of a failure to react as may occur with malaria in the winter. In all cases the rigor has commenced within half an hour to an hour of injection.

6. Immunity is incidentally conferred against the typhoid group of infections.

7. In the unlikely event of any untoward symptom arising the injections can be discontinued. Malarial pyrexia cannot be stopped by quinine with the same facility.

The *disadvantages* are:—

1. The possibility of inaccessible veins, or of thrombosis occurring in a vein as the result of frequent injection into, perhaps, the only vessel accessible. This has occurred only in one case.

2. The treatment occupies rather more time than that examining of blood films for malarial parasites at intervals.

3. In the higher dosages the material as purchased is expensive.

It can, however, be made at much less expense in a suitably equipped institution laboratory if massive doses are to be used.

DIAGNOSIS OF CORONARY THROMBOSIS WITH REPORT OF A CASE.

BY LEONARD ABRAHAMSON, M.D. DUB., F.R.C.P IREL.,
JUNIOR VISITING PHYSICIAN TO MERCER'S HOSPITAL, DUBLIN; PROFESSOR OF PHARMACOLOGY, ROYAL COLLEGE OF SURGEONS IN IRELAND.

SUDDEN occlusion of the coronary arteries was regarded until recent years as synonymous with sudden death, and, with but few exceptions, as a post-mortem interest rather than as an ante-mortem clinical entity. A survey of English text-books is barren of any advance on the subject, and there is little to choose between the statement of Broadbent in 1906 that "there are no characteristic physical signs or symptoms by which thrombosis of the coronary arteries can be diagnosed" and the statement of Price [2] in 1918 that "complete and abrupt closure of a coronary artery is usually fatal. If the vessel be small the patient may recover, but the

[2] Protein Therapy and Non-specific Resistance, by William F. Petersen, M.D., p. 247.

ondition is one which is recognised with difficulty uring life."

Clifford Allbutt,[3] it is true, discussed some few f the symptoms of coronary thrombosis, but only n passing, and made very little attempt to correlate nte-mortem symptoms with post-mortem findings. A clearer vision had been displayed in 1910 by Osler [4] n the Lumleian lectures. Thus, in speaking of the se of digitalis, he refers to one type of case in which narked cardiac weakness follows an acute single ttack of angina pectoris in a comparatively healthy nan, and states that post-mortem experience shows hat the lesion in such a case is very likely to be locking of one of the coronary vessels. Further, e realised the possibility that a man may get on ery comfortably with only the main branch of one oronary. Recently, cases of coronary thrombosis ave been recorded by Gibson,[5] Coombs and Hadfield,[6] Bulmer and Mason Lamb.[7]

In the German literature cases have been recorded n which a diagnosis was possible and the patient urvived. These are referred to in Romberg's [8] ext-book, but are regarded by the author as highly xceptional.

The main advance on the subject is to be found n a prolific American literature which has sprung p in recent years. The contrast between this gap n English literature and the multiplicity of references n American journals was stressed recently by McNee,[9] riting from the Johns Hopkins Hospital, Baltimore. 'erhaps the most representative articles are those of Ierrick [10 11] in 1912 and 1919 and that of Wearn [12] n 1923.

Clinical Features of the Condition.

It is apparent from a study of the literature that ven large branches of the coronaries may be occluded ithout an immediately fatal issue, and that the atient may survive the accident by hours or days, nd in a few cases by months or years. In those who urvive there is a characteristic clinical syndrome of hich the features may be summarised as follows :

1. The patient is usually past middle life, and may or may ot have experienced previous attacks of angina pectoris.
2. The onset is abrupt, usually with pain of extreme verity and persistence, unrelated, as a rule, to food or ertion, and recognised by the patient as unlike any pain reviously experienced. The localisation varies and may e abdominal. The pain is not relieved by morphia.
3. Symptoms of shock, with anxiety, cold sweat, collapse, eble pulse, and low blood pressure. The face is ashen nd slightly but variably cyanosed.
4. Dyspnœa, sometimes sudden and urgent.
5. Nausea, vomiting, belching of gas.
6. Signs of heart failure with enlargement of the heart, dema of the lungs, congestion of liver and kidneys.
7. Pericardial friction; inconstant, but of extreme agnostic value.
8. Pyrexia and leucocytosis.
9. Variation in the electrocardiogram.

Of the articles dealing with the electrocardiograms coronary thrombosis, the most instructive are ose of Fred. M. Smith. Smith [13] reported in 1918 investigation in which an electrocardiographic udy was made on the dog following ligation of the ronary arteries. Confirmation was recorded in a rther experimental study [14] in 1920. In 1923 he ported [15] his findings in man and discussed 11 cases, cluding one in which the descending branch of the t coronary artery was ligated in the repair of a ab-wound of the heart. The curves, particularly those patients in whom tracings were taken early d at frequent intervals following the thrombosis, rresponded closely with those obtained in the dog. e most constant changes were negatively of the deflection and a decrease in the amplitude of the R S group. Similar changes have been reported Herrick,[11] Pardee,[16] who regards as diagnostic upward convexity of the S–T interval, Robinson d Hermann,[17] and Kahn.[18]

Whilst this work is suggestive, it is by no means nclusive, and further investigation is required before finite diagnostic significance can be attached to any pe of electrocardiogram.

Case Report.

J. P., a male, aged 46, was admitted to Mercer's Hospital on April 12th, 1926, under the care of Sir John Lumsden, at whose request I saw the case, and with whose kind permission I now publish it.

The patient stated that he had been suffering for 18 months with periodic attacks of precordial pain, which radiated down his left arm, leaving it numb. These attacks were related to food and to exertion. The relationship to food was so definite that he attributed his symptoms to stomach trouble. Between the attacks of pain, and still more during the attacks, there was complaint of breathlessness and of palpitation. Giddiness and faintness were noted during the bouts of pain. This pain had occurred more frequently during the week before admission and it was for it that he sought hospital treatment.

Previous Illness.—On inquiry as to venereal disease, he stated that 18 years previously he had undergone treatment —scant and haphazard—for recurrent rashes. He granted the possibility that these were of the nature of venereal infection.

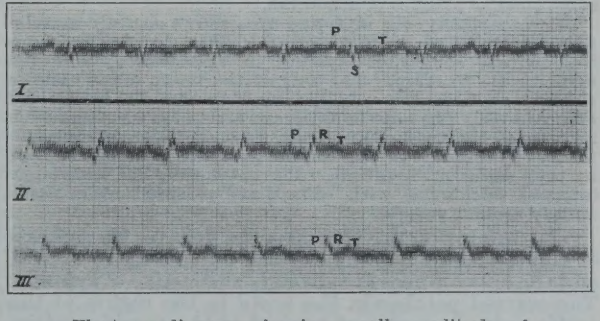
Personal and Family History.—He had been married nine years. In the first year of marriage his wife had an abortion. There were no living children. He stated that his grandfather, father, sister, and brother had all succumbed to heart disease.

History after Admission.—On arrival in hospital patient was fairly comfortable and remained so until 2 A.M., when he developed an agonising attack of pain, referred to the precordium and to the left arm. He stated that this attack was altogether more severe than and unlike any attack previously experienced. The pain lasted about 30 minutes and was accompanied by much anxiety. Seen by me on the following morning, he was ashen coloured, lips cyanosed, sweat on the forehead, with a general appearance of shock reminiscent of a case of gastric perforation. He was restless and anxious. The pulse was feeble, rate 124 per minute. The blood pressure was 110 mm. systolic. Breathing was laboured, respiration-rate 28 per minute. The temperature was subnormal. The apex beat was not palpable. Cardiac dullness extended about half an inch to the left of the nipple line. Heart sounds were almost inaudible and a faint systolic murmur was to be heard over the mitral area. The liver was enlarged and palpation over it revealed distinct tenderness. Numerous bubbling râles were heard over the bases of both lungs.

Diagnosis.—A diagnosis was made of coronary thrombosis, and the probability was suggested of antecedent syphilitic heart disease. The W.R. was carried out and was fully positive.

Progress.—Prostration was marked. Pallor persisted and delirium was noted, particularly towards night. The temperature rose on the day after admission to 99° F. and on the two following evenings registered 102°F. and 101·6° F. On April 16th it descended to 99° F. and after this

FIG. 1.



Electrocardiogram showing small amplitude of ventricular waves.

remained normal. The pulse-rate varied from 98 to 140 beats; respirations from 28 to 40 per minute. Albumin appeared in the urine. An electrocardiogram (Fig. 1) taken on April 20th, showed small amplitude of the ventricular complexes. In lead I. the S wave (no R wave is present) measures 4 mm., the T wave being represented by a barely visible depression. In leads II. and III. the R wave measures respectively 6 mm. and 5 mm., the T wave being again small but upright. Unfortunately, the condition of the patient permitted only one electrocardiographic examination.

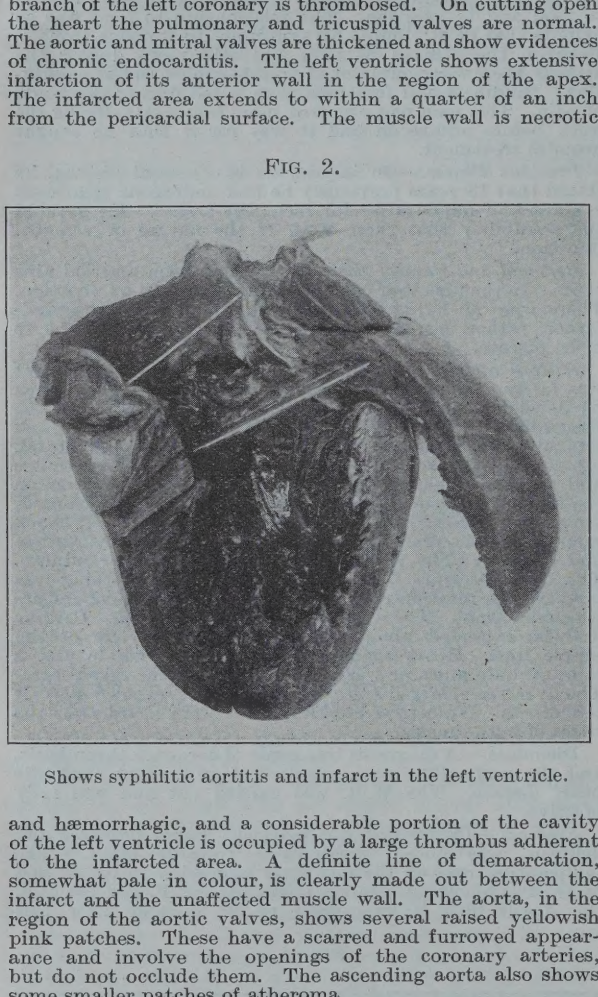
Improvement was noted on April 20th, 1926, and the blood pressure rose on this date to a systolic reading of 140 mm. This really was transient and yielded once more to prostra-

tion and delirium. On the 26th, 14 days after admission, the patient died.

Post-mortem Examination.—Only a partial post-mortem was permitted. The heart was removed by me and submitted to Dr. John Lait, to whom I am greatly indebted for the following report and the photograph (Fig. 2).

The heart is hypertrophied and when fixed weighed 22 oz. The coronary arteries are thickened and the descending branch of the left coronary is thrombosed. On cutting open the heart the pulmonary and tricuspid valves are normal. The aortic and mitral valves are thickened and show evidences of chronic endocarditis. The left ventricle shows extensive infarction of its anterior wall in the region of the apex. The infarcted area extends to within a quarter of an inch from the pericardial surface. The muscle wall is necrotic

FIG. 2.



Shows syphilitic aortitis and infarct in the left ventricle.

and hæmorrhagic, and a considerable portion of the cavity of the left ventricle is occupied by a large thrombus adherent to the infarcted area. A definite line of demarcation, somewhat pale in colour, is clearly made out between the infarct and the unaffected muscle wall. The aorta, in the region of the aortic valves, shows several raised yellowish pink patches. These have a scarred and furrowed appearance and involve the openings of the coronary arteries, but do not occlude them. The ascending aorta also shows some smaller patches of atheroma.

Microscopically, the infarcted area shows necrotic muscle-fibres with areas of hæmorrhage. The muscle-fibres are fragmented, somewhat hyaline in appearance, and the nuclei cease to stain. The rest of the heart muscle shows changes such as are usually found in chronic interstitial myocarditis. The muscle-fibres are atrophied in places with increase in the amount of fibrous tissue between the muscle-fibres. The lumen of the coronary vessels is much reduced by thickening of the intima. The patches in the aorta show internal thickening with collections of small round cells mainly around vessels.

The infarction in this case is due to thrombosis of the descending branch of the left coronary artery, and the appearances are strongly suggestive of syphilis. The scarred patches in the aorta in the region of the aortic valves are almost typical of the specific nature of the lesion. Frequent attempts to demonstrate the spirochæta by Levaditi's method proved unsuccessful.

Clinical and Laboratory Notes.

NOTE ON THE CAUSATION OF HEART SOUNDS.

BY G. ARBOUR STEPHENS, M.D. LOND.,
CONSULTING CARDIOLOGIST, KING EDWARD VII. WELSH NATIONAL MEMORIAL ASSOCIATION.

ABOUT six months ago a man of athletic build who played regularly for a senior football team presented himself for examination before being admitted to one of the local factories. On examination he was found to have a marked mitral systolic murmur without any other evidence of cardiac disturbance. He acknowledged no illness of a rheumatic nature, and stated that he felt quite fit. He was admitted to the factory on condition that he came up for re-examination in six months' time. When this period had elapsed no murmur was to be heard, but on being pressed he confessed that when previously examined he had not slept for a week, as he had been by night in charge of a mental case.

How can worry and want of sleep such as this man experienced give rise to a cardiac murmur? The answer depends entirely on what we consider to be the cause of the normal sound. If we do not know the cause of the normal heart sound how can we know the cause of the abnormal?

My explanation is as follows. In health there is about 8 c.cm. of fluid in the pericardial cavity. This fluid is under a negative pressure of about 6 c.cm. of water, and as a result of this negative pressure, to which I first drew attention [1] in 1916, there is a suction action which keeps the fluid at an equal thickness all over the heart's surface. The quality of the fluid, as well as its quantity, depends on the general metabolism of the body, and if this metabolism be disturbed by any factor, such as worry or want of sleep or both, the pericardial fluid suffers accordingly. As I have previously pointed out,[2] I consider that the heart sounds are produced by the movements of this pericardial fluid, and not by the contraction of the muscle of the heart. To produce a sound corresponding to the pitch of the normal heart sound at least 60 vibrations per second are required, whereas the heart contracts little more than 60 times per minute. If the valves cause a cardiac sound by their impact, how is it that when they are destroyed by disease and can cause no impact the sound is intensified considerably?

Fluid in a sac can be demonstrated to give rise to sounds exactly resembling those of the heart. To demonstrate these sounds all that is required is a small rubber balloon, half a teaspoonful of water, and a piece of string. Place the water in the balloon and tie the neck of the balloon as it lies quite flaccid. Place the chest piece of a stethoscope over one end of the balloon and at the same time gently press the other end with the forefinger; then the "heart sounds" will be heard.

If my contention is correct, considerable modification of present-day teaching seems to be needed.

NOTES ON

REATMENT OF NURSING MOTHERS WITH ULTRA-VIOLET RAYS.

BY CATHERINE CHISHOLM, M.D. MANCH.,

AND

MARGARET MCKILLOP, M.B., CH.B. GLASG.

As sun treatment is apparently successful in improv- general metabolism, an experiment was made at e Manchester Municipal Sun Clinic to see if ultra- olet radiation was of value in maintaining the milk pply of nursing mothers. The mothers were sent from the infant welfare clinics because breast lk was failing, and occasionally because they were ry debilitated, and it was therefore feared the milk pply would fail. The women were exposed three times week at the distance of one yard from a Hanovia ercury-vapour lamp. They were given gradually ngthening periods, from two minutes to half an ur according to the reaction of the patient. Treat- ent was then continued at the latter rate, or reduced once a week, according to the progress or needs the patient. The patients were exposed down to e umbilicus and up to the thighs, half the time posing the front, then turning.

It is difficult to treat nursing mothers at a clinic here regular attendance three times a week is pected. They have many other duties, and are ble to miss treatment because of their own ill- alth or that of their families. These mothers often d to come considerable journeys for their treat- ent, and their tram fares were also an additional pense to poor people. The patients were of all ades of the working class, the majority, but not all, the dole; some, however, were in fairly comfort- le circumstances. They had to attend three times week, and if they did not do so with fair regularity eir treatment was discontinued. It was not con- ered, especially during the early period when the posure is short, that a less attendance than three es a week would be of value. That so many sisted under these circumstances shows that they mselves felt they were deriving benefit from the atment. Of the first 100 cases treated after ne 1st, 1926, 47 ceased to attend within a month one reason or another. As no benefit could be sonably expected unless a regular course was ten, these cases are not further considered in this ort.

n treating these women we looked for improvement he general health. This alone, in so far as it made woman more fit to undertake maternal and house- ery duties, would justify treatment. But we were oing also for improvement in the breast supply, or preservation for some time when it seemed to be ing. It was expected that its vitamin content uld be enhanced by exposure of the mother to light, so that not only would there be a greater, a better, supply.

Of the cases who persisted in treatment, 53 in nber, all experienced general benefit. In 11 cases, vever, no benefit so far as breast milk was con- ned was obvious, although in two cases the mothers l they felt better for a time. Of the 11 cases, one her had breast abscesses and had to give up; ther was absent for a time from ill-health, and refore failure was not unexpected; one mother off nursing her children with tonsillitis; three s appeared to improve slightly for a time; one ned her child owing to her private doctor's advice. he remaining 36 cases all were successful in improv- or retaining milk-supply for prolonged periods. rt notes of a few cases are appended.

aby, 9 weeks. Supply, which was failing, improved second treatment.

aby, 1 month. Baby supp. feeds of Glaxo. Mother r fed her babies more than three weeks before, and anxious to continue. In a month on breast only, and gaining well.

Baby, 10 weeks. Breast and Cow and Gate. Within fort- night milk better. Mother's health improved. Hb. index went up from 70 per cent. to 80 per cent. Breast milk increased. Baby's weight markedly improved, though C. and G. feeds were not increased.

Baby, 14 weeks. Started treatment 16/7/26—milk fail- ing. 21/7/26 breast milk test feed ¾ oz. 27/8/26 breast milk 2 oz. No supplementary feeds given. Breast fed till 7 months.

Baby, 3½ months. Mother, 31—losing milk. In month baby entirely breast fed, and mother not taking so much in the way of extra feeds. Baby breast fed entirely to 9 months.

Baby, 2 months. Breast milk failing. Milk improved and baby partly breast fed till 7 months.

Baby, 3 months. Mother giving only one breast feed a day was persuaded though without faith in treatment to attend. In three weeks was giving only two bottles in 24 hours. Later report gives milk still increasing.

Baby, 1 month. Breast fed alternately with C. and G. A week later note says mother only gave three artificial feeds since treatment began. At 7 months the notes say breast milk beginning to fail, baby has *one* bottle a day. Improvement later shows baby now 8 months entirely breast fed.

Our acknowledgments are due to the medical officer of health for permission to publish these cases.

A CASE OF

SUBACUTE YELLOW ATROPHY OF THE LIVER.

BY ANDREW BROWN, M.B., CH.B. GLASG.,
LATE MEDICAL OFFICER, COLONIAL MEDICAL SERVICE.

THE following was an interesting case.

A native male (Barotse) was admitted to the Livingstone Hospital, Northern Rhodesia, in December, 1925, suffering from general weakness, loss of appetite, and swelling of the abdomen. He stated that his illness began about three months before admission, and that his condition was rapidly becoming worse. He had always been employed as a cattleman, and could give no clue as to the cause.

Examination revealed great enlargement of the liver, emaciation, and slight yellowness of the conjunctivæ. There was only a small amount of free fluid in the abdomen, and the urine was apparently normal. The lower margin of the liver was palpable about 3 inches below the costal margin. The palpable area of the liver was covered with numerous large nodules, firm in consistence, and only slightly tender on pressure, varying in size from 1 to 3 inches in diameter. A needle was inserted into several of the larger masses, but no fluid was obtained. A small quantity of fluid was withdrawn from the abdominal cavity, and it possessed the characteristics of ordinary ascitic fluid; tyrosin was not present in this fluid. The liver gradually became more enlarged, the quantity of free fluid greatly increased, necessitating frequent aspiration, and emaciation became extreme. The patient died from exhaustion on Feb. 6th, 1926, about eight weeks after admission.

Post-mortem examination showed very great enlargement of the liver (weight 14½ lb.). The kidneys were slightly enlarged, pale, and capsule slightly adherent. The other organs were apparently normal. The outer surface of the liver was coarsely mottled—dark, irregular areas alternating with lighter yellowish patches—and firm in consistency. Other portions of the liver were softer, and on section exhibited soft, somewhat circular patches, filled with yellowish semi-solid tissue. Sections prepared from specimens gave markedly different appearances representing different stages in one pathological process. In some areas the liver cells were swollen and granular, the nuclei staining faintly, and the cell margins appearing indefinite. Many of the cells contained pigment. In other places all traces of cell-structure were absent, only a granular debris remaining. In more advanced stages all traces of the liver tissue had disappeared, the lobules being represented by the fine connective tissue framework. In some parts connective tissue proliferation and round-cell infiltration was marked, and there was also some proliferation of bile-ducts.

These findings would indicate a subacute yellow atrophy of the liver.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT EDINBURGH.

(*Continued from p. 193.*)

MONDAY AND TUESDAY, JULY 18TH AND 19TH.

REPRESENTATIVE MEETING.

The Duties of Medical Officers of Public Schools.

THE report of the proceedings in committee, dealing with the Council's recommendations on school medical officers, was received and approved. Therein the duties and remuneration of whole-time and part-time medical officers of public schools were defined and it was established that they should be appointed by, be directly responsible to, and have direct access to the governing body, also that satisfactory arrangements should be made in school curricula for health instruction and that the medical officer should be consulted in framing the syllabus.

Antenatal Work and the General Practitioner.

Dr. RENTON then brought forward his postponed amendment to refer the whole subject of the Midwives Act, 1918, back to the Council for reconsideration in the interests of all concerned with antenatal work. He said that the five parties concerned were the unborn child, the expectant mother, the general practitioner, the public, and the midwife. Former speakers had stated that if only the general practitioner would make himself efficient in this work he had the solution in his own hands. The experience of practitioners was that they had made themselves efficient only to be passed over. Midwives were being trained, by a three-days' course, to undertake the whole of the antenatal work. The county medical officer of the speaker's district was not unsympathetic but said that he could do nothing with the Midwives Act as it stood.—Dr. H. M. RAVEN seconded the motion and Sir EWAN MACLEAN cordially supported it, saying that it was a matter of common agreement that antenatal work was the principal avenue to the reduction of puerperal morbidity and mortality in this country. The people who ought to have this matter in hand were unquestionably the general practitioners, notwithstanding any further development of antenatal clinics or the education of midwives. They were not only willing but anxious to take part in this life-saving work. Their alleged shortcomings had unfortunately been one of the propagandist features of those seeking to establish clinics. This was a profound mistake, and any scheme which left them out of account was sure to fail.—Dr. D. ROXBURGH supported the motion from the point of view of the efficiency of the practitioner.—Dr. BONE said that the practical problem was how to get the general practitioner to do the antenatal work, and accepted the motion.

Application of the Scale of Public Health Salaries to Scottish Appointments.

The Chairman of Council reported that the Council had that day passed the following resolution:

1. That the scale of minimum commencing salaries for whole-time public health appointments amended in the manner suggested by the Scottish Committee—namely: (*a*) that the commencing salary for resident medical officers be £250 to £400, plus emoluments; (*b*) that the commencing salary of medical officers employed in departments be on a graded scale, the average salary over ten years being not less than £600, the minimum commencing salary to be not less than £500; (*c*) that the scale of commencing salaries for chief medical officers of health be as follows:—

Population not exceeding	50,000	=	£800 to £900
,, ,, ,,	100,000	=	£900 to £1100
,, ,, ,,	250,000	=	£1100 to £1400
,, exceeding	250,000	=	£1400 to £1600

(*d*) that a minimum commencing salary of not less than £700 may be recognised in county areas with a population not exceeding 25,000, where coördination with an adjoining area is not feasible, be accepted for application to Scottish public health appoi ments as a working arrangement for one year only as fr June 16th, 1927; and

2. That in the meantime the Council authorise Conference of Representatives of British Medical Associat and Society of Medical Officers of Health to consider modification of the scale, for application to public hea appointments in England, Scotland, and Wales on following lines: That there be added to the scale a note the effect that as an alternative to the existing provisi of the scale relative to the salary of "medical offic employed in departments" there would be accepted for su officers an initial salary of £500 a year if the appointmen made on a definite scale under which, subject to satisfact service, the officer appointed would receive annual inc ments of not less than £25 (or biennial increments of less than £50) rising to not less than £750 a year.

Resolved that the action of the Council be approv

Puerperal Pyrexia Regulations.

A motion by St. Pancras—

(1) That the minimum fee payable to a recognised obste specialist for each consultation under the Puerperal Pyre Scheme be £3 3*s.* (excluding operative treatment), w reasonable additions for mileage to be mutually arranged w the local authorities; (2) that the Representative Body i opinion that the local authority should be empowered the Ministry of Health to pay a reasonable fee to the gen practitioner who meets in consultation an expert calle under the Puerperal Pyrexia Regulations; and (3) tha be an instruction to the Council to take all possible step secure that these resolutions be made effective,

was thrown out after some attempts to amend it h been discussed. It was opposed by Drs. MASTERM BONE, and HAWTHORNE, and was variously descril as "grotesque" and "the most unreasonable mot ever put forward."—Dr. D. ROXBURGH and I. W. JOHNSON supported it.

Bath put forward a motion to ensure that kinds of specialists should be included in the pa of consultants under these regulations. Sev speakers, including Dr. R. BOYD (Manchester) Dr. W. F. DEARDEN (Manchester), were anxious t the general practitioner should be eligible for th panels, as he was the man with most experience the condition. After some verbal emendation this sense the Bath motion was agreed to as follo

That it is desirable, owing to the fact that puer pyrexia may be due to causes other than obstetric, any panel of consultants which may be instituted u the Regulations should include competent physic surgeons, and pathologists, in addition to consulting ob ricians; further, that some standard of competence sh be adopted, such as membership of the staff of a general or obstetric hospital, or the possession of sp qualifications or experience by private practitioners.

Remuneration of Assistants.

In 1925 the Representative Body drew u tentative scale of remuneration for assistant general practice, but decided to take no active s to enforce it at present. A motion from the So Eastern Counties of Scotland desired to modify scale, while another from St. Pancras desire enforce it by the refusal of advertisements which not conform. Dr. J. S. MUIR, speaking for the motion, urged the difficult conditions of rural pra and the fact that an assistantship was so much of the training of a young doctor that the sugg salary of £240 per annum with board and lodging unnecessarily high. It would make it impossibl many busy men to employ an assistant at all.—Dr Cox spoke of the office difficulties aroused by scale, as plenty of advertisements, both from empl and employee, were received offering and asking than the scale. He hoped that the Represent Body would stabilise the position.—Dr. BONE poi out that the B.M.A. was often twitted with se up scales for whole-time officers and none for its assistants. A tentative policy had been achieved this was not the moment to make it rigid. first motion was rejected and the second withdr

Reports to Coroners.

Dr. J. G. MACQUEEN (Hyde) and Dr. R. B. S (Ashton-under-Lyne) proposed and carried a moti

That there should be a fee where a report has requested by a coroner from a practitioner who h

ormed a post-mortem examination and who is not called ive evidence.

r. Macqueen pointed out that in his district it was stantly happening that a report was demanded er these circumstances.—Dr. BONE replied that had always been the policy of the Association had been pressed in vain during the recent otiations. He did not think another opportunity ld arise for 50 years. The only remedy was to se to give such a report.

Nursing Home Bill.

ir RICHARD LUCE reminded the meeting that the ared policy of the Association had been that sing homes belonging to doctors should not be ected or registered. The Select Committee, ever, had not thought that it would be feasible doctors to be thus exempted. The Council had e to the same conclusion and was not taking any s to get special exemption in the Bill at present re Parliament. This Bill provided that the ecting authority should be the county or borough ncil, but an attempt was being made to impose duty on anybody that had control over maternity are, which would put it in the power of very much ller authorities. The Select Committee agreed it was essential for the inspecting officer to have status of M.O.H. of a county or borough.

Overseas Branches.

ir JENNER VERRALL, Chairman of the Overseas mittee, proposed and carried without discussion report on this subject.

General Medical Council.

r. MORSE brought forward a motion from rnemouth—

at the question of the need for revision of the existing esentation, power, and procedure of the General cal Council in order that they may comply more isely with the changed conditions of medical practice, emitted to the Council for consideration and report.

r. BONE offered to accept this motion on behalf he Council, but the meeting decided to pass to next business.

Encroachment Upon Private Practice.

uch feeling was aroused by Brighton's motion :

at the Representative Body, viewing with considerable ern the insidious inroads continually being made on te medical practice under the auspices of the State, ntary bodies, and others, and being of opinion that this t only detrimental to the interests of the individual bers of the medical profession, but ultimately to all s in the community, instructs the Council to watch all developments and actively to interest itself in safe- ling private practice amongst all groups in the medical ssion and to develop through the branches and divisions r coöperation with the local medical profession for purpose.

. E. R. FOTHERGILL enumerated a long list of nples of directions in which the work of the ral practitioner was being filched away, and said the practice of 100 years ago would very soon e to exist. If a medical man had no practice for years he became rusty ; in ten years he was a er. Before long all general practitioners would this position. The General Medical Council and tate seemed to be at cross purposes ; the former ed students to do all kinds of medical work, the r wanted a team of whole-time officers to work r the medical officer of health. This silent, less, but plausible encroachment on the private itioner had to be stopped. The private prac- ner must be retained ; he had an ideal in his life a trust in his hands as much as the clergyman or other profession and it was as well to announce Were medical men going to have a chance to that ideal in the future or were they going to be poned, regularised, and controlled until they had eedom of action or freedom of practice ?

M. E. B. TURNER supported the motion from his years of experience both of practice and of ork of sundry bodies concerned in public health ities. To say that the general practitioner could not do the work as well as the whole-time man was sheer utter nonsense. If he chose to take it up he could do it as well and better than most of the young practitioners who were appointed. Administratively, no doubt, the whole-time practitioner was "tamer" and easier to work. Contract work was not the ideal ; the ideal was the work done between the medical practitioner and his patient, but the younger generation of doctors were being educated to expect a good deal of contract work. The medical profession, concluded Mr. Turner, was skidding on a very slippery slope at the bottom of which there was nothing but a cemetery in which would be buried all that made the profession worth while. The only thing that could arise from that cemetery was the spectre of a whole-time State Medical Service, which would take all the humanity out of the profession and leave instead an icicle wrapped up in red tape called an inspector.

Dr. H. WOODROFFE supported the motion, instancing midwifery work, to which many general practitioners looked for the jam on their bread and butter ; this was being filched steadily away.

Dr. C. E. DOUGLAS (Fife) strongly deprecated the suggestion that "the best doctor was he who could send you to the appropriate specialist." If that was right the practitioner, instead of being the skilled and trusted adviser of his patient, would become nothing more or less than a medical shopwalker directing customers to the appropriate department.

Tunbridge Wells brought forward a similar motion, which was finally amended to read—

That the Representative Body views with anxiety the increasing tendency to transfer the treatment of many diseases and conditions to whole-time medical officers as being detrimental to the public health, and refers to the Council the consideration of the general adoption of the following principles: (1) The function of the health authority should be confined as much as possible to the prevention of disease. (2) The work of the whole-time officer should be confined to administration, inspection, institutional, or consultative work. (3) Health visitors and nurses should be definitely responsible to a local practitioner for patients dealt with by them, including expectant mothers.

Dr. E. A. STARLING, proposing the motion, said that it was not an attack on public health medical services ; the practice of medicine was one and existed for the public good. But some of the inroads made under the ægis of whole-time medical officers were not for the public good.

Dr. E. WARD, speaking as one who had been in general practice for 10 years and a whole-time officer for 14, referred to the difficulty of getting the general practitioner to take up and keep up these part-time posts. He was sure that the difficulties could be adjusted and that it was a matter for goodwill and getting together. Joint conferences might very well take up the problem of how the private practitioner could more and more be taken into the public health service.

Dr. D. ROXBURGH, Dr. M. RAVEN, and Dr. J. A. MACDONALD also supported the motion, and both the Brighton and the Tunbridge Wells motions were carried.

Married Medical Women.

Dr. S. FARMER proposed on behalf of Bishop Auckland—

That the Representative Body seriously deprecates the recent action of the Durham County Council in dismissing one of its women medical officers from its staff on the ground of her recent marriage, and is of opinion that if marriage is to be a cause for dismissal this should be stated at the time of appointment.

Whereupon an amendment proposed by Dr. CHRISTINE MURRELL (Kensington) was seconded by Dr. E. K. LE FLEMING (Southampton), to delete the words after "marriage" and insert instead the words, "and reaffirms the Association's policy of equality of status and salary for medical men and women." Dr. Murrell said that the last clause might be taken to face both ways, and if it were admitted that a woman might be dismissed on grounds of marriage public health authorities would not be slow to take

the hint. It was not a question of whether women should continue to work after marriage but whether they should be debarred from it, whether they were to be legislated for or allowed to come to their own decision. The question of individual liberty was involved. Dr. Le Fleming reminded the meeting that the Association had always held the policy of equality and that the capacity for doing his or her job should be the only critical factor. The amendment was carried. Whereupon Mr. BISHOP HARMAN, saying that this was sitting in judgment on a body in a matter of which the meeting had no personal cognisance, proposed and carried an amendment to phrase the motion as follows :

That the Representative Body reaffirms the Association's policy of equality of status and salary for medical men and women.

In reply to a question as to what this had to do with the original motion, the CHAIRMAN said that the first four words were unaltered. Dr. MURRELL appealed to the sense of fairness of the meeting and challenged them not to be afraid of saying what they really meant. She was successful in carrying as a substantive motion (seconded by Dr. P. MACDONALD, of York)—

That the Representative Body seriously deprecates the action of any local authority in dismissing one of its women medical officers on the ground of marriage and reaffirms the policy of the Association of equality of status and salary for medical men and women.

Lunacy Law and Administration.

Dr. LANGDON-DOWN, Chairman of the Lunacy Law and Mental Disorder Committee, presented a special memorandum on this subject prepared for the Representative Body. It dealt with two separate but interdependent subjects, he said, viz., the protection recommended for medical practitioners signing certificates and the facilities recommended for treating patients. In both these respects the Committee felt that the Royal Commission's report was unsatisfactory. Fortunately, there was very general agreement as to the requirements. At the present time the atmosphere was very favourable to increased protection for the doctor and greater freedom of procedure in treatment. The speaker referred to the recent pronouncement of Mr. Justice McCardie, and added that difference arose, however, when it came to the best methods of securing the objects in view. While it was desired to remove the intervention of the judicial authority, safeguards must be preserved through inspection, registration, and control from the Board of Control. One of the most important results of the Royal Commission was that the Board, after considerable attack, had emerged with greater prestige than ever before. The proposed loosening of the shackles was in the interest of both patient and doctor. All the proposals which tended to accentuate judicial interference seemed to be in a retrograde direction. The profession must always stand for intimate relationship between doctor and patient. He grouped the possible courses of action into four : 1. The demand for the concession of witness-status for the certifying practitioner. This was passed at the Representative Body in 1924. 2. Strengthening the Lunacy Act to the end of warding off civil actions. The Royal Commission had proposed that the onus of proof should rest on the plaintiff and that action should not lie unless the plaintiff could satisfy a judge in chambers that there was prima facie ground for his case. The Committee wished to add to this recommendation the proposal that the judge in chambers should be assisted by a competent medical assessor. The Committee also supported the recommendation of the Commission that, where the justice was called on to sign a certificate, he should cease to be perfunctory and be compelled to take measures to satisfy himself that the practitioner had exercised reasonable care. 3. The establishment of a body of certifying Government official doctors. 4. That the profession should shelter behind public officers so that the duty of care should not lie upon it. The only justification for the idea of witness-status was that in a sense it could be held that the judicial authority was holding a court, but such a conception was in the interests of the patient and was contrary the profession's general ideas of progress in treatment of mental disorder. Complete immun for the doctor meant that he was not open to att even if he had not shown reasonable care. Un the common law of England all experts had to g reasonable care. The claim had been urged bef the Royal Commission by the B.M.A. representativ but the Commission had decided to advise protect of the doctor by the second method. As an ame ment had been put into the agenda of the Represen tive Meeting reiterating the demand for witn status, Dr. Langdon-Down emphasised the unreas ableness of going to Parliament, against the rec mendations of the Commission, to ask for relief fr the duty of reasonable care. (The amendment withdrawn subsequently.) He pointed out that witness status would not hold under the Urge Order where the justice was not called upon, under the few days' Provisional Order. There m be some protection to cover all the host of acti which doctors had to meet in which the witn status would not save them even though the jus was called in. The second method would co everything done under the Act and would go as as was possible without repudiating the duty of c The third method would mean that a doctor always to go to a relieving officer or public off before he could deal with these patients, w would be quite impossible in private prac Another amendment had suggested using a th of non-coöperation to enforce the profession's vi Dr. Langdon-Down thought it would be a mistak enforce any particular solution, particularly a moment when the public was so favourable to profession, as it might produce a situation different from that desired. (This amendment also withdrawn.) He thought doctors would get necessary protection if the recommendations of report were put into effect. He wished memorandum referred to Council, as it dealt many very delicate legal matters.

Dr. J. NEAL, who had withdrawn the two am ments from Hendon mentioned above, suppo Dr. C. O. HAWTHORNE in his amendment, w read :

That the Representatives thank the Lunacy Law Mental Disorder Committee for the memorandum o report of the Royal Commission on Lunacy Law and M Disorder, refer it to the Council, and request the Co to reappoint the Committee with instructions to whatever steps are possible to secure what the report c Royal Commission declares to be "fair," namely, tha medical profession should not be asked "to perform essential part under the menace of litigation which, e unsuccessful, may spell financial or professional ruin."

Dr. Hawthorne protested against the sugge that there was any desire in the profession to es responsibility for professional action duly taken. Commission had failed to find a single case of wro certification. He objected to giving approval printed document in general, as such things liable to come home to roost in particular.

Dr. Neal said that greater protection was esse but not absolute immunity. Deliberate negli should not be protected, but no action shoul possible without reasonable cause. Shifting the of proof to the plaintiff was excellent as far went and would very considerably modify the posi Medical assessors might prove very valuable, b was an experiment the worth of which only could prove. There still remained, however, a grave danger—viz., that a doctor might be proce against under the law of libel, not under the Lu Act at all. The certificate was medical evidence, w if given in a court, would be protected. He that certifying practitioners should not be subj to a living nightmare as they were at present.

Dr. W. GRIFFITH (Marylebone) said that his div had heard the views of its experts and unanim demanded complete protection. The menace ha been removed.

r. BONE urged the Representative Body to take opportunity of saying definitely what it wanted. ry doctor wanted protection, and the judges and ybody else were in agreement. The whole stion was how to obtain it, and that was the stion the meeting ought to answer. To send the norandum back was to burke an obvious duty. case for witness-status had been put as well as sible and fully discussed, and the Commission had rted that on grounds of public policy it was not ible. The interests of the profession were subary to the general interest. Under these circumnces the Representative Body must decide whether withdraw from its original position or whether to its back to the wall and demand witness-status nothing. The Committee did not think that shifting onus of proof was enough, but the choice of the lical assessor might prove a difficult one, as it ned that money would buy any opinion from some lical experts. How was it possible for an honest lical opinion to be given 10 or 12 years after the nt? One method of attacking the problem ht lie in preventing the profession from giving h evidence. He asked the meeting to turn down Hawthorne's amendment and put up something nite for discussion.

r. H. G. HAYNES (mid-Essex) emphasised the fact t the Royal Commission had dismissed the question witness-status and that before the next Representa- Meeting new legislation might be put into force. protection of the practitioner was not the only g in the report.

r. H. C. BRISTOWE (Bristol) recalled that at the e when the Act was being discussed the profession regarded the protection it afforded as very nearly plete; experience had proved that it was not. thought that witness-status should be demanded, n if it could not be obtained.

r. E. R. FOTHERGILL said that his experience that when a judge had the opportunity of using chnical assessor he did not take it. He thought suggestion, that the magistrate should certify the practitioner had exercised reasonable care, a most dangerous one. The first thing to urge that the patient needed treatment. It would most disastrous to bring the judicial authority any medical question. It had never been decided whom the doctor was responsible, whether to the ent or to someone who asked him to examine patient. If it was to the patient, then the ificate should be handed to him; if to the nds, then the doctor was open to a libel action. question ought to be plainly discussed.

r. A. NOBBS (Wandsworth) asked for an account hat occurred between the B.M.A. representatives the Royal Commission. The weak spot in the was that the magistrate, who knew nothing of hiatry, was required to protect himself, the ent, and the general practitioner.

r. D. ROXBURGH said that this was a battle royal een doctors and lawyers, and doctors should for complete immunity from all civil actions.

r. F. RADCLIFFE supported Dr. Hawthorne's ndment. He pointed out that if a doctor ined a recluse patient under the order of a istrate he was open to an action for assault and no redress. This case was not mentioned in the orandum. Nor was the single-care case. The demanded that the certificate should be signed he usual medical attendant, but then debarred from treating the patient any longer. Often the reason why this type of case was certified under e care was that he might be kept at home under ontinued care of his own doctor.

r. LANGDON-DOWN undertook to convey to the mittee the opinions expressed. The Committee, lly composed of general practitioners and others, discussed Dr. Hawthorne's views fully, but had been able to accept them. In speaking of the ce of litigation, Dr. Hawthorne had taken a graph from the report of the Royal Commission out its context. Dr. Langdon-Down accepted the amendment, as he himself desired that the memorandum should go to the Council for reconsideration and improvement, on the understanding that the last clause was not to tie their hands. The amendment was carried.

Dr. F. TEMPLE GREY (Marylebone) said that Dr. Hawthorne's amendment was not sufficiently precise. The doctors would do their case more harm than good by refusing to sign certificates and would be lacking in their duty if they tried to avoid this responsibility. The immunity Dr. Hawthorne had asked for was not imaginary but existed in Scotland and had existed in England. He moved:

That it be referred to Council to consider the desirability of urging upon the legislature that the judicial authority under the Lunacy Act of 1890 must assume full responsibility for the commitment of a person alleged to be of unsound mind, and that such judicial authority be either a county court judge or a magistrate with special qualifications, such as a medical barrister.

The people of these islands would only agree to detention under due process of law. It was only as the funds of medical defence unions became large that the magistrate ceased to admit this responsibility. It was important to press, not for what was vaguely called "witness status," but for the acceptance of responsibility by the magistrate, as in Scotland.

This was seconded by Dr. W. GRIFFITH (Marylebone), and Dr. L. D. PARSONS observed that this was the law in Ceylon. The motion was passed.

Dr. D. ROXBURGH then proposed:

That the Representative Body directs the Council to appoint a Committee for the further consideration of the report of the Royal Commission on Lunacy; and further directs the Council to secure on the Committee an adequate number of general practitioners on whom the responsibility of signing certificates under the Lunacy Acts mainly falls.

Dr. LANGDON-DOWN accepted this and it was carried.

Parliamentary Elections.

The Chairman of the Parliamentary Elections Committee (Dr. E. K. LE FLEMING) said that the most important place of all to make known professional views was the House of Commons. The Ministry of Health was not the House of Commons. Very few Members of that House even knew or understood what the B.M.A. was and stood for, and many had the most extraordinary views of its constitution. If a medical man became a Member of Parliament he generally developed rapidly into a politician and ceased to represent the views of the profession at large. In Sir Richard Luce the profession had a very valuable exception to this rule. This Committee of the B.M.A. had been allowed to languish. The Council had seriously considered winding it up, but at a recent meeting the trustees of the National Insurance Defence Trust had placed a sum of £1000 at the disposal of the B.M.A. Committee for the support of approved medical candidates for Parliament. The Council therefore recommended:

That the Council be authorised to accept the offer of the trustees of the National Insurance Defence Trust, and to adjust the composition and procedure of the Parliamentary Elections Committee accordingly.

That the Representative Body express the opinion that in view of the offer of the trustees of the National Insurance Defence Trust members be urged to contribute to the Medical Representation in Parliament Fund so that the volume of individual contributions to that fund shall reach a total at least equal to the promised contribution of the trustees of the National Insurance Defence Trust.

Dr. JOHNSON SMYTH supported these recommendations.—Dr. E. K. LE FLEMING then pointed out that the Association had no politics but it was extremely difficult to get party backing for medical candidates. This difficulty was less in university seats, where party feeling ran less high. He therefore proposed:

That the Parliamentary Elections Committee be instructed to pay special attention to the possibility of securing the election to Parliament of medical candidates for University seats.

These motions were all carried and the report approved.

Public Health Propaganda.

Dr. LEWIS LLOYD, Chairman of the Public Health Committee, proposed and carried :

(i) That medical practitioners should not give health lectures under the ægis of local authorities gratuitously; and (ii) that although the lecturer must in every case necessarily be approved by the local authority there is no reason why any particular class of practitioner should be excluded from delivering such lectures.

He also stated that the scheme of coöperation between the B.M.A. and the Society of Medical Officers of Health, agreed to in 1923, was under consideration. It had been decided that the offices of the Association and Society should keep each other advised in all matters relating to prospective public health appointments, and that the Society should make it clear to all its members that any action taken locally must be by and through the British Medical Association Division. In 1926 the Council had been instructed to consider how local branches of the Association could contribute to public health education. As a result of consideration of Sir G. Newman's memorandum on this subject, and of consultation with the Society of Medical Officers of Health, it had been agreed to suggest to the divisions that they approach their local authorities with a scheme for health propaganda work. This scheme, he said, would include lectures and cinema demonstrations on the obvious subjects of general medical interest, elucidation of local problems, visits to dairy farms, hospitals, holiday camps, and health exhibitions, and distribution of propaganda. The Society of Medical Officers of Health had proposed, he said, that its scheme for propaganda and that of the Association might be complementary if the divisions of the Association would interest themselves in the following proposal : The setting up by the Society of a committee to advise local authorities in reference to the education of the public and to promote health education work, the committee to consist of 12 members representative of the obvious State and municipal bodies concerned, and to invite medical officers of health to secure subvention from their councils. The Society proposed, if adequate financial support were forthcoming, to appoint for trial a half-time assistant secretary for propaganda purposes.

Dr. LEWIS LLOYD moved that the report and proposal should be approved.

When the report had been approved, Southport proposed :

That the Council be asked to arrange with the Society of Medical Officers of Health that, in areas where cases of small-pox are known to exist, special propaganda work for vaccination should be organised.

Dr. F. J. BAILDON reported an anti-vaccinationist propaganda in Southport and carried his motion. Dr. LEWIS LLOYD said that as a profession doctors were behindhand in making themselves acquainted with the latest information about small-pox statistics.

Poor-law Reform.

While Dr. H. B. BRACKENBURY, as Chairman of the Poor-law Reform Committee, was proposing the adoption of this part of the report of Council, the chair was taken by Dr. C. O. HAWTHORNE.

Dr. Brackenbury said that in June the Ministry of Health had withdrawn their previous proposals, approved by the Representative Body last year, and substituted an entirely new set. These were tentative, and not yet in the form of a Parliamentary Bill. The cardinal principle with which the Association was concerned was the unification of all forms of health administration within the local authority. The new proposals did not give as good an opportunity for this as did the old ones, except in the areas known as county boroughs. Instead of boards of guardians being abolished, they were to persist under more convenient areas and forms of election. The Association had insisted that it was desirable for a health committee to be empowered to coöpt members of the medical profession or others interested in health administration. Educational bodies had the statutory obligation thus to coöpt. The new proposals allo county councils, boards of guardians, and commit of management of Poor-law hospitals to coöpt pers experienced in the administration of the Poor-l It was much more important to have on these c mittees people experienced in hospital administrat and pressure should be brought to bear in direction. In reply to a question, Dr. Brackenb explained that under the new proposals Poor- institutions would be transferred to the cou council and managed by special committees, t thirds appointed by the Council and one-third by board of guardians.

National Health Insurance : Ophthalmic Clinics

Dr. H. G. DAIN, Chairman of the Insurance A Committee, said that agreement had been reac over several matters which had caused anxiety. future a patient wishing to change his doctor wo have to give a fortnight's notice and submit insurance card to be stamped. This would prev his leaving hurriedly in a " huff," and would do a with canvassing for medical cards. It was also ho that a satisfactory disciplinary scheme would soo proposed. Trouble had been caused by the very la number of claims for treatment under ophtha benefit. Dr. Dain then proposed :—

That the Representative Body approves the princip providing ophthalmic benefit through clinics in large ce as an arrangement auxiliary to the existing schem attendance by ophthalmic surgeons privately, subjec the arrangements under which such clinics are establ being approved by the Council.

He said that this was a departure from a prin to which the Representative Body was very fi wedded, that of extending consultant services on lines of private practice. He warned them that was the first special service included in Nati Health Insurance benefit, and considerable w was likely to be given to it in future arguments.

Dr. R. WALLACE HENRY (Leicester) remi them that the approved society now decided wh the patient should go to an ophthalmic surgeo an optician. When the optician was unable to e with the case he sent a certificate to the societ be forwarded to the ophthalmic surgeon. societies were saying that it was only financial cir stances which made them send patients to opti first, and the number was growing so large th was becoming impossible for them to pay guinea fee for the surgeon. As a result, 70–8 cent. of insured people were sent direct to opti Some of the societies had set up ophthalmic c already, and some of the younger oculists had acc appointments to them. If the Council had pe sion to go into the matter, it might be possi formulate a satisfactory scheme for providing thalmic benefit through medical men to pract the whole insured population. If this could be the weight of opinion in favour of sending pa to opticians would be turned round, and the majority of people would go to the oculist. G. W. KENDALL (City) supported the motion said the change of policy was of great impo to the whole profession. Ophthalmic surgeons in favour of it. Dr. E. J. PRIMROSE (Glasgow that the wording of the motion would give r the impression that a new and different princip being accepted. The principle involved was t giving private attendance to insured patients modified fee. He suggested amending the m in this sense. The great reduction in fee in in the clinic arrangement was only admissible society really was in an impoverished state should not be allowed to become universal.

It was agreed to substitute " suggestion " principle " in the first line of the motion a add " in certain circumstances " after " centre the second line, Dr. Dain accepting this amend

Dr. P. MACDONALD (York) warned the m not to blink the fact that clinics had come t and would be extended in other directions.

ost of the work under the Insurance Acts would be ne on clinic lines.

Dr. E. E. BRIERLEY (Cardiff) said that the ophthalc surgeons of Cardiff took the report of Council to licate that the clinic cases would be those that d been to opticians first. To examine ten such ses in two hours would be impossible. They also nsidered that the already reduced fee was being ively diminished when they were expected to see ht or ten serious cases at 8*s.* 6*d.* per head. conded by Dr. J. D. WILLIAMSON (Cardiff), Dr. ierley proposed, therefore,

That the Council be asked to consider whether the number new cases should be eight rather than ten.

This was carried, as was also a motion by Maryle-ne:

That the Council be requested to urge the Ministry of alth to provide for extended benefits under the National alth Insurance Acts.

Dr. Dain said this had already been urged peatedly; it was a question of money and money ly.

Hospitals.

The Chairman of the Hospitals Committee, Mr. . S. SOUTTAR, moved and carried without discussion,

That where the remuneration of a consultant for regular riodic visits to a Poor-law hospital is on a salary basis, e amount of that salary should be a matter of arrangement tween representatives of the local medical profession and e appointing authority, but regard should be had to the nimum fees laid down at the annual representative meeting, 26, and/or to the basis of £2 12*s.* 6*d.* for consultant sessions not more than two hours, with an allowance for mileage ere necessary.

Mr. Souttar then said that the policy of the Asso-ation was that any payment a patient made in spital was for treatment and not for maintenance. certain paragraphs of the voluntary hospital licy appeared to weaken this position, he proposed at they be deleted. This was carried without scussion. He then proposed—

That specialist work in connexion with the treatment of tients suffering from mental disease in its early stages ether at hospitals or clinics should not be carried out by ole-time medical officers of public health or local govern-nt authorities, but on a part-time basis by medical practi-ners who have special knowledge of the subject, but who o not necessarily be devoting their whole time to such cial work.

This motion had called forth a strong letter of otest from the Royal Medico-Psychological Associa-n. Mr. Souttar said that the last thing the B.M.A. shed to do was to give the impression that they nted to exclude any group of medical men from eir proper work, but it was the declared policy of e Association that as far as possible medical work ould be carried out by private practitioners. Such rk should not be transferred from general practi-ners to those holding full-time appointments under blic authorities, but there was no wish to exclude ole-time men.

Dr. E. W. MASTERMAN (Camberwell) and Dr. J. W. LLESPIE (Belfast) proposed to amend the resolution inserting the word "necessarily" in the phrase hould not be carried out by whole-time medical cers," and to cut out the last phrase. The motion amended was accepted by the Chairman.

In proposing the remainder of the report under Hospitals," Mr. Souttar said that the hospitals had t the Association over the two points of difficulty—., that patients should take to hospital with them ers from their practitioners, and that hospitals uld be used as far as possible in a consultative acity.

It was agreed, on the motion of Salisbury,

That the Representative Body instructs the Council to sider the formulation of a middle-class hospital policy.

Contributory Schemes.

Dr. Fothergill then proposed on behalf of Brighton inclusive motion in reprobation of the inroads ng made into private medical practice "by the contributory schemes which are springing up all over the country." He reminded his hearers of the evils of the old club practice days, and said that a similar position was now developing in the hospitals. Doctors were told to make their money out of the kudos of being on the staff. There was no satisfactory income limit for hospital patients, no representation of the doctor on the club scheme, and no free choice of doctor by the patient. There were now 120 of these organisations in existence, and 90 of them had definite contracts with the hospitals, entirely opposed to the B.M.A. policy. Soon the hospitals would be arranging for the specialist to see the patient in his own home. A man who paid a guinea a year to insure his house against fire was not a pauper when his house was burnt down. It should be held that when the clubs had paid premiums the patients were not objects of charity.

Mr. Souttar said the proposal had his sympathy and the matter was serious, but there was this difference from club practice: that the hospital practitioners were unpaid for their services. It was difficult to get hospital staffs to take any interest in the matter. As these proposals covered a great deal of ground he suggested their being referred to Council. Dr. Fothergill agreed to this.

Naval and Military.

Sir RICHARD LUCE, chairman of this committee, said there had been an increased allowance this year to officers serving in India, but efforts to make the grant retrospective had failed. There had been difficulty in getting enough recruits, for which there was now no real reason. The arrangement that men might take one year of their service in hospital was bearing good fruit.

Earlier in the meeting Sir RICHARD LUCE had proposed and Dr. F. GOODBODY seconded,

That the Representative Body of the British Medical Association, assembled in Edinburgh, congratulates Captain C. H. Vernon, a member of the Association, on having won the King's prize at Bisley for the year 1927.

This was carried with applause.

Dr. J. F. WALKER, chairman of the Charities Committee, presented the report under that heading.

The reports of the Scottish, Welsh, and Irish Committees were approved without discussion.

The secretary announced that Dr. E. A. STARLING, of Tunbridge Wells, had been elected to the Council in place of Dr. Arnold Lyndon, who, on his election to the deputy chairmanship of the representative body, became *ex officio* a member.

The following were elected to Council by the representative body: Dr. R. Langdon-Down, Sir Richard Luce, Dr. F. J. Baildon, Dr. J. A. Macdonald, Dr. J. W. Bone, Dr. H. G. Dain, Dr. C. E. Douglas, and Mr. W. McAdam Eccles.

Cordial votes of thanks were passed to the local hosts who had helped to make the stay of the representatives so pleasant, to the staff, and to the chairman, Dr. Brackenbury, who, in closing the meeting, invested his successor, Dr. C. O. Hawthorne, with the badge of office.

ANNUAL GENERAL MEETING AND PRESIDENT'S ADDRESS.

The ninety-fifth annual general meeting was held on Tuesday, July 19th. Mr. R. G. Hogarth, retiring President, took the chair, and inducted his successor, Sir Robert Philip. The President-elect, Sir Ewan Maclean, was introduced and promised the hospitality of Cardiff for 1928. The Chairman of Council, Sir Robert Bolam, proposed a vote of thanks to Mr. Hogarth, and said he had proved an astonishingly able and vigorous President. The meeting then adjourned till 8 P.M., when the President delivered in the Usher Hall, Lothian-road, the address which appeared in our last issue. Dr. Fergus Hewat, honorary

local general secretary, presented to the President delegates from the Canadian, American, and China Medical Association, and a large number of foreign and overseas guests. The Sir Charles Hastings Clinical Prize was handed to Dr. J. S. Manson, of Warrington. A vote of thanks to the President was proposed by Dr. C. O. Hawthorne and seconded by Sir Alfred Ewing, Principal and Vice-Chancellor of the University of Edinburgh. Afterwards a very large gathering was received by Sir Robert and Lady Philip in the McEwan Hall. Those who wished to dance went on from there to the Palais de Danse, Fountainbridge.

ANNUAL DINNER.

The annual dinner, held on July 21st in the Music Hall, George-street, was more largely attended than ever before. Sir Robert Philip, who presided, was supported by the Lord Provost of Edinburgh, Lord Dawson of Penn, the Sheriff of Edinburgh and the Lothians, Earl Russell, Lord Sands, the Principal of the University, the Moderator of the Church of Scotland, the Presidents of the Royal Colleges of Physicians and Surgeons of Edinburgh, the chief officers of the Association, and others. The President was escorted to the dais by four pipers from the Edinburgh postal band, and later in the evening the haggis was accorded the same honour. Lord Dawson, who proposed the health of the Imperial Forces, spoke of the close association of the warrior and the doctor from Homeric times down to the recent war. He mentioned particularly the magnificent war service of the drifters. Rear-Admiral Bowring, in acknowledging the toast, referred to the great reduction in mortality and morbidity rates among sailors in recent years, and expressed the gratitude of the Services for the work of the medical profession. Economy in the navy, he said, was not the feeling of any responsible body of people. The toast of "The City of Edinburgh" was proposed in French by Prof. Tuffier, of Paris, who complimented the city on its beauty and its association with the great name of Lister. The Lord Provost, in replying, remarked on the pride which Edinburgh had always felt in its medical school. The 600-years-old alliance between France and Scotland had, he said, left its impress on these nations; thrift was a feature they had in common. Lord Sands, toasting the Association, described a visit to the island of Cos, which had served as a base hospital in the Trojan war. His own earliest associations with the Edinburgh medical school were coupled with the name of Dr. James Gregory. Medicine had, he feared, lost some of its picturesqueness since that time. Sir Robert Bolam's acknowledgment of this toast was, he said, the last act of a retiring executive chairman. Whether holding office or not, he would find some way of working for the honour and interests of the medical profession. The President of the Canadian Medical Association, Dr. H. S. Birkett, proposing the health of Sir Robert Philip, reminded him that McGill University had been founded by four Edinburgh graduates.

LISTER CENTENARY CELEBRATIONS.

Wednesday, July 20th, was the day specially set apart for the commemoration of Lord Lister. The University of Edinburgh held a reception in the afternoon in the Old Quadrangle. The upper library of this building was devoted throughout the week to a fine display of personal and professional relics of Lister, as well as copies of old surgical woodcuts, engravings of Edinburgh medical worthies, and other objects of interest. In the evening the McEwan Hall was almost filled with the varied colours of academic robes and evening dress for the principal celebration. The chair was taken by the Earl of Balfour, who delivered an eulogy of Lister. He remarked on Lister's enduring affection for the two Scottish Universities which had given him his opportunity. Lister would have been a great surgeon at any period of the world's history, but he owed his unique eminence to his association with Simpson and Pasteur. Without chlorof he could not have developed his surgical techni and without knowledge of the action of putrefac bacteria he would not have directed his atten towards the means of combating those enemies the surgeon. The services which Pasteur, Simps and Lister had rendered to mankind could not estimated; they were outside all machinery comparative valuation.

Sir William Watson Cheyne described the c trast between surgical wards before and after the w of Pasteur and Lister and went on to say that th had been nothing accidental about Lister's wo As a dresser he had been horrified by a severe break of gangrene in the wards and had never gotten it. Pasteur's work had given him suffici solution of the mystery to enable him to deve a technique for the prevention of wound sep It was a striking example of the practical value pure science. Lister's contributions to the ra expansion of surgery were obscured by the greatn of his antiseptic work. He was a pioneer in exp mental pathology.

Prof. Tuffier said it was not too much to cla that the discoveries of Pasteur and Lister, appl by surgeons and physicians for 50 years, had sa as many lives as there were people in all the wo He offered to the memory of Lister the loyal gratit of all French surgeons.

Prof. Harvey Cushing delivered the address "Emancipators," which was printed in full in last issue.

Prof. John Stewart (Halifax, N.S.) said t simplicity was the keynote of Lister's life and wo he loved music and children and had a keen se of humour. A certain aloofness was due to shyne he was anything but cold and indifferent at he He always carried about with him an air of otl worldliness, but the main depression clouding last years was chiefly due, he thought, to a se of loneliness, a mistrust of modifications of routine which were arising and the lack of recogni of his fundamental work in pathology.

Lord Balfour announced that the prize for best essay on "The Influence of Lister on Surge had been awarded to Mr. George W. Gale, and t the Royal Colleges of Edinburgh had conceived scheme of erecting an institute to the memory Lister.

EXCURSIONS AND SOCIAL AMENITIES.

The Sunday excursion for representatives took form of a long motor tour through the Scott coun including a view over Dryburgh Abbey. The p was entertained to tea at Floors Castle, the sea the Duke of Roxburgh. The sun shone and visibility was so good as to make the magnifi views from "Scott's point" and Soutra Hill finer than usual. On Monday evening "The Doct Dilemma" and "Rob Roy" were played to houses. There was dancing at the Palais de D each night, and the number of special excursion places of historical and æsthetic interest was ex tionally large. By special invitation the R Scottish Academy was open to members of Association for a private view on Thursday eve while for others Mrs. Kennedy Fraser and her p gave a special concert of Hebridean music. the President and members of the Edinburgh Br of the Association received a large number of vis at the Palais de Danse, where Highland and Low dancing was kept up till a late hour. A novel plea was the reception by the Lord Provost and m trates of the City of Edinburgh at the Sco Zoological Park. The rain held off, and visitors able to spend the long northern evening stro round this beautiful menagerie. An after reception was held on Thursday by the Ladies' A ciation at Inverleith House in the Botanical Gar and another on Friday by the Royal Medical So at its house in Melbourne Place.

EXHIBITION OF INSTRUMENTS, DRUGS, FOODS, AND APPLIANCES.

The usual exhibition was held in the Waverley Market from July 18th to the 22nd, and was larger than ever before. The market provided a light and spacious hall, and the abundance of flowers was a particularly pleasant feature. At the official opening on Tuesday, July 19th, the chairman of the Representative Body, Dr. H. B. Brackenbury, referred to the value of publicity and introduced Sir Robert Philip, President-elect of the Association, who declared the exhibition open. He commented on the fundamental necessity to medicine of the correlation of the vision of doctors and experimenters with the ingenuity of technicians. That happy union had been notably exemplified during the past century by the two firms of J. F. Macfarlan and J. Gardner and Son, both of which were exhibiting this year and both of which had been associated with Lord Lister. An account of the stands will be given in a later issue.

Reviews and Notices of Books.

COMPARATIVE PHYSIOLOGY.

The Genetics of Sexuality in Animals. By F. A. E. CREW, M.D., D.Sc., Ph.D., Director of the Animal Breeding Research Department and Lecturer in Genetics in the University of Edinburgh. Cambridge University Press. 1927. With 37 text figures. Pp. 188. 10*s.* 6*d.*

Dr. Crew writes very good books. Himself an active experimenter, he also has the gift of exposition, and he gives here in moderate compass a clear and interesting outline of a subject to which few people are indifferent. The first part describes the chromosome mechanism of sex determination which has been unravelled during the last 25 years. This he regards as now being settled, at any rate for a time. He passes on to discuss the physiology of sexual differentiation, the means that is by which the chromosome composition of an individual gains its expression in secondary sexual characters. All the cells of the body are either male or female according to their equipment in sex chromosomes. In insects this leads directly to the development of the sexual characters which constitute the maleness or femaleness of an individual; sex glands take no part in the process, and a male caterpillar will develop into a male moth whether it is left alone, castrated, or has an ovary implanted in place of its testis. But in mammals, as everyone knows, the sex of an individual depends not only on the sex chromosomes of the cells of which the body is composed, but on the presence of functional sexual glands, and in a vaguer way on the thyroid and other endocrine organs. The great problem which now lies open for inquiry is the nature of this connexion between the sex of an individual and the sex of his cells, and Dr. Crew's discussion of the facts at present available and his indication of the lines along which progress may be looked for is very suggestive. In one form or another he makes good deal of use of Dr. R. Goldschmidt's idea of time scale, which naturally leads on to chapters on sex reversal and intersexuality. Medical men would have been glad of a discussion of the sexual effect of the adrenal tumours which come within their province; the subject has been clarified lately by the demonstration that femaleness may be regained the surgeon removes the growth. Finally, there is chapter on the sex ratio which no one will read without wanting to find out why males die more easily than females from early fœtal life onwards. We hope that the recent extensions of his department at Edinburgh will enable Dr. Crew to find the answers to some of the many questions which he raises. Useful bibliographies are included.

THE CLINICAL INTERPRETATION OF THE WASSERMANN REACTION.

By ROBERT A. KILDUFFE, A.B., A.M., M.D., Director of Laboratories, Atlantic City Hospital; City Bacteriologist Atlantic City, N.J., &c. Philadelphia and New York: Lea and Febiger. 1926. Pp. 203. $2.50.

THE author considers the whole question of the Wassermann reaction, beginning with its basic principles. He deals with the many problems that confront clinician and serologist alike, such as the fact that a W.R. may be positive one day and negative a few days later. There is adequate and interesting discussion on the complement-fixation reaction in pregnancy, and in neurosyphilis. A whole chapter is given up to non-luetic conditions giving false positive reactions; an equally useful chapter treats of false negative reactions. Dr. Kilduffe holds, as do all good pathologists, "that the results of the test must be interpreted in conjunction with all the other findings of the case at hand." Considering the W.R. as a test of cure, the writer emphasises that fact that a negative reaction is merely an indication of the condition at the moment, "bears no guarantee for the future, and holds no promise of permanency." Dr. Kilduffe notes that for any complement-fixation report to be of value, the test must have been carried out by a worker with extensive training and experience.

It is difficult in a short review to show just how good, and how well worth reading, is this little book.

PYELOGRAPHY: ITS HISTORY, TECHNIQUE, USES, AND DANGERS.

By ALEX. E. ROCHE, M.A., M.D., M.Ch. Camb., F.R.C.S. Eng., Chief Assistant to a Surgical Unit, St. Bartholomew's Hospital. London: H. K. Lewis and Co., Ltd. 1927. Pp. 118. 9*s.*

THIS little book, which is founded on the somewhat slender basis of 58 personally observed pyelographies, draws largely on the experience of other observers, notably Braasch, and will prove useful to those who are learning to practise this branch of diagnostic technique. Beginning with a short account of the history of pyelographic examination of the kidneys, the author proceeds to describe the method, the solutions used, and some of the difficulties which may be met with. A series of chapters follows, in which the value of pyelography in relation to the various forms of renal disease is discussed, and the deductions arrived at are illustrated by plates.

As a well-arranged summary of the work which has been done on its subject, Mr. Roche's book has its value; the author does not claim to add to our knowledge. An introduction is contributed by Sir John Thomson-Walker.

OPHTHALMOLOGY.

Applied Refraction. By HOMER ERASTUS SMITH, M.D., Assistant Surgeon, Manhattan Eye, Ear and Throat Hospital. New York: William Wood and Co. 1927. Pp. 131.

THE first thing that strikes us about this book is the entire absence of any but the most casual reference to the method of retinoscopy which to refractionists in this country has long served as their sheet anchor in the preliminary examination for glasses. Except for a few pages on the ophthalmometer, an expensive instrument which is admittedly not infallible, this author relies entirely on subjective tests. This is the more surprising in that he insists on the need for cycloplegia in any patient who has evidence of eyestrain, and this, he says, "be he seven or seventy." Indeed, according to him, in the later decades of life with a small residuum of focusing power left, the need for cycloplegia is even more urgent. This need he attributes to the unequal action of the ciliary muscle in its several meridia—a segmental action which may

partially counteract an astigmatism only revealed when the accommodation is paralysed. That this segmental action exists is not generally admitted, though in support of the theory that it does a physiological experiment of Hensen and Voelkers (the latter name misprinted in this book) may be cited. Textbooks on refraction are generally discreetly silent on this point, though by their insistence on the necessity for complete cycloplegia for the correction of small astigmatic errors they implicitly support the theory that segmental accommodation is possible. An apparatus for testing the visual acuity under varying degrees of illumination is illustrated in Dr. Smith's book, and this should be useful, not only for testing the light sense, but in connexion with the prescription of tinted glasses for patients unusually sensitive to glare. The cyclophoria which sometimes is troublesome when oblique cylinders are prescribed is discussed. The relative advantages of different forms of bifocal lenses are pointed out, and there is a final chapter on the cosmetic value of glasses. We cannot recommend this little book as a complete guide to the art of refraction. At the same time anyone engaged in this work will find it worth reading, since it contains information and advice on many practical points which are not ordinarily alluded to in the text-books. Its unconventional style is a further recommendation.

Saving Eyesight after Mid-life. By J. HERBERT WHITE, M.D., Instructor in Ophthalmology in the Harvard Medical School, Cambridge (Mass.). Harvard University Press. 1927. Pp. 48. 4*s.* 6*d.*

THIS little book is one of a series termed "Harvard Health Talks," and is addressed to the general reader and more especially to the middle aged. It is principally occupied with a popular exposition of glaucoma, and informs readers of the insidious nature of that disease in its chronic form. One-third of all blindness in America arising after middle life is said to be due to this disease, and the chief purpose of the book is to warn the public that periodic examination by an oculist is necessary even though vision may be apparently normal, and to reassure them as to the chances of a permanent good effect of an operation undertaken in time.

DISEASES OF THE DIGESTIVE ORGANS.

Fourth edition. By CHARLES D. AARON, M.D., F.A.C.P., Professor of Gastro-enterology in the Detroit College of Medicine and Surgery. Philadelphia: Lea and Febiger. 1927. Pp. 1964. $11.

THE new edition of this American text-book preserves the general character of its predecessors. The book is too verbose to make a strong appeal to many English readers, but it is a merit that some mention, if only a brief note, is made of nearly every subject that can in any way be associated with the alimentary canal. The author gives no description of phytobezoars, Snapper's test for porphyrins, or the blood-sugar curves after lævulose feeding in cases of hepatic deficiency. But we have no doubt that these minutiæ will appear in future editions. The printing and illustrations are excellent.

JOURNALS.

JOURNAL OF PATHOLOGY AND BACTERIOLOGY. Vol. XXX., No. 3, July, 1927.—Interference Phenomena in the Action of Chemotherapeutic Agents in Trypanosome Infections, by C. H. Browning and R. Gulbrausen (Glasgow). Parafuchsin will kill *T. brucei* in mice: so will trypaflavin. But trypaflavin will not act in animals which have previously received a non-sterilising dose of parafuchsin. The therapeutic action of other substances—e.g., arsacetin—is also interfered with by parafuchsin.—The Titration of Scarlet Fever Antitoxin in Rabbits, by H. J. Parish and C. C. Okell (Beckenham). It is difficult to measure the antitoxic value of sera prepared with the scarlet fever streptococcus by their capacity to neutralise toxin in animals, but satisfactory titration can be achieved by testing their efficacy to protect rabbits against the septicæmia produced by the streptococcus itself. The values thus obtained show close agreement with human Schultz-Charlton and therapeutic tests.—Osteoclastoma (Myeloid Sarcoma) of the Human Female Breast, by H. J. B. Fry (London). A case of this rather rare tumour containing sarcomatous fibrous tissue, cartilage, osteoid tissue, and giant cells of myeloid type, with a good discussion and account of the literature.—A Statistical Study of Relapse in Enteric Fever and Erysipelas, by M. Young (London). Working on data from the Belvidere Fever Hospital, Glasgow, it appears that relapsing cases do not differ from non-relapsing cases in the duration of or degree of febrile disturbance in the primary attack. The relapse is on the average about half as long as the primary. The interval between primary and relapse tends to be longer as the primary attack is longer, and there is a slight relationship between the severity of the primary and that of the relapse.—A New Design of Porcelain Filter, by C. E. Jenkins (Salford). Adapted to filter a few c.cm. of liquid with very little loss.—Diphtheria Bacilli in Bile, by J. McCunn and A. M. L. Greaves (London). Pure cultures of *Corynebacterium diphtheriæ* were obtained from an acute cholecystitis at operation.—Cross Immunity with Rat Tumours, by S. Russ and G. M. Scott (London). Rats inoculated with tumour cells killed by X rays show afterwards a considerable degree of resistance to the implantation of the same and also of some other tumours.—Microscopic Evidence of the Different Manner of Clumping of Motile Bacteria with Somatic and Flagellar Agglutinins, by J. A. Arkwright (London). With flagellar agglutinin the bacilli are immobilised; with somatic agglutinin the free flagella continue to move the adherent bacilli.—Lamb Dysentery, by T. Dalling (Beckenham). Toxin-antitoxin mixtures given to the ewes reduces the lamb mortality from 8 to 0·9 per cent.; anti-welchii serum given to the lambs reduces it from 16 to 0·2 per cent.—Seasonal Variation in Pneumococcal Virulence, by J. F. Gaskell (Cambridge). The virulence of laboratory cultures regularly falls in the summer and reaches its maximum in the pneumonia season, December to April.—The Determination of Virulence of Pneumococci Freshly Isolated from Human Lesions, by C. H. Whittle (Cambridge). A few subcultures on agar or egg do not alter the virulence.—Demonstration of *Spironema pallida* in the Nervous System, by G. W. T. H. Fleming (Dorchester). Jahnel's method is tedious but gives good results.—A Case of Unrecognised Cancer of the Breast, by C. J. Polson (Manchester). A small scirrhous cancer of the right breast gave rise to large masses of growth in the abdomen apparently via the lymphatics of the thoracic wall and the umbilicus.—A Qualitative Chemical Differentiation of Thyroid Secretion from Thyroid Colloid, by G. S. Williamson and I. H. Pearse (London). The secretion of the active adenoid tissue contains no biological iodine as colloid does.—Adenocarcinoma of the Ovary in a Hen, by J. Gordon and F. C. Happold (Leeds).—A Rapid Method of Examining Tissue Microscopically for Malignancy, by B. T. Terry (Nashville, U.S.A.). Thick freehand sections are stained on one side only with polychrome methylene blue.—Proceedings of the Pathological Society of Great Britain and Ireland.—This issue of the journal contains a portrait of A. Balles Lee, some extra copies of which may be had from the editor at 17, Loom-lane, Radlett, Herts.

BIRTHDAY HONOURS.—In the list of recipients of Birthday Honours published in THE LANCET of June 11 (p. 1247) we regret the omission of the name of Alfred Geddes Tresidder, Major, I.M.S., who was appointed a Companion of the Indian Empire. Major Tresidder is surgeon to H.E. the Governor of Bombay, and aural surgeon to the Gokuldas Tejpal Hospital, Bombay, and the Sassoon Hospital, Poona.

THE LANCET.

LONDON, SATURDAY, JULY 30, 1927.

LUNACY LAWS AMENDMENT.

A LEADING article in the *Times*, aptly entitled "The Lunatic at Large," drew public attention recently to the need for lunacy law reform. This article elicited a congratulatory letter from Dr. J. S. RISIEN RUSSELL, in which he conveyed the suggestion that medical practitioners "ought not to be vested with their present powers, but that they should be required to appear before a judicial authority and give evidence on oath as to the grounds for certification, as is required in any other class of case in which a doctor has to give evidence." Dr. C. O. HAWTHORNE, Chairman-elect of the Representative Body of the British Medical Association, said that the sole "power" that a doctor possesses in these matters is to give a written opinion or certificate to the effect that in his judgment the patient is of unsound mind and requires to be restrained either in his own interest or in the interest of the community. When such a certificate is placed with other relevant documents before the proper judicial authority (a specially selected magistrate) it is open to that authority to make or not to make an order for the patient's detention. It is the magistrate, not the doctor, who has the power to restrain the patient. The present power vested in the doctor is the signing of a professional certificate; if this is taken away every case of certification will become a judicial inquiry with copious evidence from experts and with corresponding expense and waste of professional time. Already, under the Act of 1890, the magistrate can require the certifying medical practitioner and any other witness to appear before him and give evidence on oath. The machinery of Dr. RISIEN RUSSELL'S proposal therefore exists if the magistrates consider that the interests of the patient or the public require its operation.

At the meeting of the British Medical Association the Section of Mental Diseases held a discussion jointly with the Royal Medico-Psychological Association on the recent report of the Lunacy Commission. This was opened by Dr. G. M. ROBERTSON, President of the Royal College of Physicians of Edinburgh, whose words as an ex-president of the Association and a leading psychiatrist carried weight with the meeting, as they had previously carried weight with the Royal Commission responsible for the Report. Dr. ROBERTSON found that the Provisional Treatment Order, the second of the procedures recommended in the Report for the involuntary treatment of mental cases, was open to serious criticism in that the signature of one doctor alone was required. The doctor would often be a general practitioner, and might possess little experience in the treatment of mental cases, but the procedure was to be legalised by the intervention of a justice of the peace who would have no medical experience whatever. He held that the addition of the legal authority in no way served the interest of the patient, laid stress on the absence of proved cases of improper detention as taking away the argument for the intervention of the justice, and urged that for the purposes of the Provisional Treatment Order the justice of the peace should be replaced by the Board of Control. Several speakers on the same and other grounds favoured the elimination of the judicial authority unless it were possible to select magistrates with knowledge of the subject, and to provide through local authorities specialists to assist the general practitioner. Dr. RISIEN RUSSELL welcomed the Provisional Treatment Order as supplying the medical profession with a claim for protection, and thought that the examination of the patient by a legal authority would be an advantage; if the justice had no medical training he would view the matter from a standpoint different from the medical one. This argument was countered by an explanation from Earl RUSSELL, a member of the Royal Commission on Lunacy Reform, who interpreted the recommendation of the Report as the introduction of a pure formality to meet public apprehensions which must prevail with the legislature. He pointed out that a vast body of uninformed and uneducated public opinion regarded doctors as too ready to certify, and, while it was needless or undesirable for the justice in these circumstances to have medical knowledge, the part he was asked to play was still useful, his duty being to see, and simply to see, that due care had been taken in the patient's behalf, and that all the legal papers were in order. But Earl RUSSELL looked also at the Board of Control as the real safeguard, and so came into line with the view that involuntary treatment was not an infringement of a patient's liberty to be compared with detention in other circumstances. This valuable discussion closed without any formal summing-up or resolutions, but its general outcome was, in spite of the critical remarks here alluded to, an expression of satisfaction with the Report. The objections to the introduction upon the scene of the justice of the peace for the main part were based upon the views of clinicians that any circumstances which embarrassed the rapid commencement of treatment in respect of early mental disease ought to be anxiously avoided, and it is to be hoped that ultimate legislation will reflect this view.

It is a fallacy to suppose that the proceedings under the Lunacy Act are or can be entirely assimilated to other judicial proceedings. The grievance of the certified patient, which takes the form of actions such as Harnett *v.* Bond or De Freville *v.* Dill, is that he has wrongfully been deprived of his liberty. There can be no analogy to the common law action for damages for wrongful imprisonment. In the nature of things lunacy proceedings have the essential peculiarity that the lunatic cannot conduct anything like a defence to the allegation of lunacy. In every other form of judicial proceeding anyone in the position of a defendant is entitled to a clear statement of the allegations made against him, and is entitled to make his reply thereto. In lunacy proceedings this is impossible; moreover, considerations of urgency seldom permit the dilatory and protracted preliminaries of ordinary judicial actions. But if the analogy of lunacy cases to ordinary judicial trials cannot be pressed, it remains the fact that doctors who certify a lunatic are no more than witnesses who supply evidence upon which—as in ordinary criminal or civil trials—a judicial authority makes up its mind. At present the medical practitioner is being asked to certify at the risk of an unlimited personal liability in damages—a threat or penalty to which no other kind of witness is exposed. This is the point at which the lunacy law must be reformed if the country does not desire to see doctors deterred by a series of adverse verdicts from volunteering their evidence in future. The medical

profession has nothing to reproach itself with unless it be the fact that medical science has not yet surmounted the almost impossible obstacles in the way of evolving a standard definition and standard tests of insanity. If such tests were available the certifying doctor who had applied them might at least feel more safe from ex-post-facto criticisms launched with the support of members of his own profession.

THE NEW DIPLOMA IN BACTERIOLOGY.

THE Senate of the University of London have instituted an academic diploma in bacteriology, and the London School of Hygiene and Tropical Medicine as we recently announced, have, as from Oct. 4th next, provided a full-time course in advanced bacteriology covering one academic year. Bacteriology thus takes its place as a recognised subject of post-graduate study, and this recognition cannot fail to alter materially the status of an important branch of science. Technological study of bacterial life, whether in its relation to epidemiology, to agriculture, to brewing, or to the preparation of leather, has prepared the way for the study on its own account of the life history of one of the most interesting groups of the vegetable kingdom. Such study is overdue. Pathological bacteriology is already hampered by the limitation of our knowledge on fundamental bacteriological matters, but the lacuna is not felt only by medical science, and entrance to the prescribed course is not to be confined in any way to those possessing a medical qualification. Such limitation would indeed be altogether undesirable, for though the paternity of medicine is clearly stamped on the growing science, it has already advanced well beyond parental control, and must set up house for itself. The diploma is open to graduates in medicine, science, or pharmacy of London or of any other approved university. Registered medical practitioners or other non-graduate students who have obtained a qualification and undergone a previous training which, in the opinion of the University, has fitted them to profit by the course, may be admitted after individual approval. At the same time the University has recognised that the training necessary for a medical bacteriologist differs in essential respects from that required by a student who proposes to apply his knowledge of bacteriology in some other direction, and the course of study, as well as the examination for the diploma, is divided into two parts. In the first the student will be concerned with bacteriological principles and with general technique. In the second he will study the application of these principles to clinical medicine, to hygiene, or to industry, as the case may be. Each student will be required to select one of these three special branches of study when entering for the course. It is probable that the teaching of applied bacteriology will, in time, be undertaken by different schools of the University whose staff and equipment enable them to deal effectively with particular aspects of this diffuse and widely ranging subject. Now that a start has been made, facilities will inevitably grow with the demand, but in the immediate future it seems likely that the majority of the students will be concerned with the application of bacteriology to medicine or hygiene, since facilities for the teaching of such students are already available.

All those who are concerned with medical science will, we think, welcome the advance which has been made. The provision of adequate facilities or study in London was the first essential step, but no one familiar with medical education will dispute that the creation of an academic diploma is a natural development, in the absence of which the attempt at serious teaching might well have been abortive. If a post-graduate student is to devote a complete academic year to the study of his subject, it is right that he should receive some mark of his attainment upon the satisfactory completion of his course, and though we all recognise the faults and limitations of the examination system, a satisfactory substitute has yet to be found. With the London diploma following so soon upon the similar diploma at Manchester, it will not be long before every applicant for a bacteriological post will be expected to present evidence of adequate training in his subject. In this connexion we would urge the extreme importance of maintaining a high standard of attainment. It is an altogether mistaken view that a diploma course is, of necessity, in some way inferior to a course leading to a degree. A course of instruction can be anything that teachers and examiners like to make it; the higher the standard set, the greater will be the attraction to the best type of student. London is the natural home within the Empire of serious post-graduate study, and it is of the first importance that the distinction which it can confer should not be cheaply won. We note with satisfaction the regulation which states that a mark of distinction will be placed against the name of those candidates who show exceptional merit. The convention that candidates at a diploma examination should be dealt with as though they showed a dead level of attainment has done a good deal to stultify post-graduate study. The pass level, even a high one, falls short of academic distinction and the student who has done exceptionally well deserves to have that fact recorded.

Events of the last few years suggest that a renaissance of bacteriology is at hand, and at the moment the demand for skilled workers from various parts of the British Commonwealth has outstripped the available supply. The stimulus given by the academic recognition now accorded to the subject by the Senate of London University should presage a revival of interest in an essential branch of science. The London School of Hygiene and Tropical Medicine are to be congratulated on having so opportunely made provision for meeting the serious shortage of trained bacteriologists by establishing a course of study under Prof. W. W. C. TOPLEY, at No. 6, Gordon-square, in October next, instead of waiting for the opening of their new building. The temporary department should tide over a period which, it is hoped, will not exceed two years.

THE CAUSE OF ACROMEGALY.

IN diseases which are comparatively uncommon and run a long course it is unusual for an autopsy to be done under the direction of those who have observed the case over a long period. Special interest therefore, attaches to a recent monograph [1] in which Harvey Cushing and L. M. Davidoff record four cases of acromegaly, with complete clinical histories and post-mortem findings. Their observations are of considerable importance. As they rightly point out among the criteria essential to the definition of any disease as an entity is the association with it of definite histopathological changes in a certain organ or organs; and to be convincing these changes

[1] Rockefeller Monograph No. 22, 1927.

must in no case shrink beyond a certain minimum. In acromegaly it has been difficult to identify the morbid lesion which causes the distinctive overgrowth, the difficulty being due to the variable secondary symptoms of the malady and still more to its widespread pathological manifestations. The chief argument has centred round the ætiological rôle of the hypophysis, and a notable advance was made when H. M. Evans and J. A. Long [2] brought forward dependable proof that the hormone of growth, which alone can account for acromegaly and gigantism, is secreted by the epithelial portion of the gland, and almost certainly by the chromophilic cells of the anterior lobe.[3] Further evidence has been gradually accumulating from the examination of fragments of hypophyseal adenomata removed at operation in cases of acromegaly, and valuable information about the histology of the hypophyseal lesion has been obtained. From the examination of 35 such cases in Cushing's clinic, P. Bailey and L. M. Davidoff [4] showed that chromophilic cells containing distinctive granules are always found in such cases, whereas in the types of adenoma associated with non-acromegalic manifestations the cells are invariably chromophobe in character. The hyperpituitary conception of acromegaly has therefore considerable support, but much is still obscure. The post-mortem findings described in Cushing and Davidoff's monograph throw a considerable amount of light on the problem. The four cases were of different clinical types, and illustrate the kaleidoscopic nature of the disease. In one patient, a man of huge frame, the general splanchnomegaly and widespread changes in the endocrine series quite overshadowed the small hypophyseal lesion. In another, an acromegalic giant, the picture was dominated by symptoms due to the neighbourhood of the tumour. The two other patients were small. In one of them an enormous intracranial adenoma, unsuspected during life, was unasked by cardiovascular and diabetic symptoms, and autopsy revealed adenomata in many of the ductless glands. In the other, a woman who died from diabetic coma, the post-mortem findings were relatively insignificant and the hypophyseal tumour was small. The only constant findings in all the cases were the commonly recognised overgrowth of the mesodermal tissue, the less commonly emphasised and disproportionate splanchnomegaly, the more or less general polyglandular anomalies, accompanied by a tendency to adenomatoses, and a central hyperplasia (two cases), or an adenoma of the hypophysis (two cases). In all four cases the cells composing the lesion contained demonstrable acidophilic granules, and the authors believe that these features are always present in acromegaly. They state that extracts of the part of the gland in which these cells are situated are capable of producing, in an experimental animal, overgrowth not only of the mesoblastic tissues but splanchnomegaly as well, together with changes in the ductless glands comparable to those seen in acromegaly and gigantism. They consider that the anterior lobe of the hypophysis is the keystone of the endocrine arch, and regard it as almost certain that a hormone from its granular acidophilic cells is the cause of acromegaly and gigantism in man.

Annotations.

"Ne quid nimis."

THE SOCIETY OF APOTHECARIES AND THE TEACHING OF MIDWIFERY.

THE Examinations Committee of the Society of Apothecaries of London has drawn up a report which is to be presented shortly to the Court of Assistants of the Society and which predicates a departure of great educational interest in the work of the Society. For this report recommends the Society to institute at an early date a diploma indicating specialised knowledge of the subjects of antenatal care, midwifery, and infant welfare. The diploma it is proposed to grant to registered medical practitioners who have been engaged in post-graduate study of the particular subjects, both in practice and theory, and a high standard of professional knowledge will be guaranteed by a stringent examinational test. It is intended to leave no doubt whatever as to the intensive character of the work done by the candidates for the new diploma, or as to the character of the examination being one of honours standard. The movement of the Society is one that will meet with general approval, for such a diploma will be specially adapted to the needs of the practitioner. Apart from the fact that a doctor may wish to show that he possesses a knowledge and experience in these subjects of a higher grade than that demanded for legal qualification, the acquisition by a large number of doctors of the diploma must lead to a higher standard generally of gynæcological training. How much this is needed has been the subject of debate in the proceedings of the General Medical Council and before medical societies on many occasions, when the lack of opportunities afforded to medical students for the sound study of obstetrics and gynæcology has been a matter of general regret, and has been seen to present educational and institutional problems that cry for solution. The invitation of the Society of Apothecaries to the post-graduate study of these subjects is therefore timely.

PHOSPHATIC CALCULI AND DIET.

PHOSPHATIC calculi, forming stones in the bladder of rats, seem to have been first associated with a dietetic cause by T. B. Osborne and L. B. Mendel [1] in 1917. They noticed the occasional occurrence of stones among their experimental animals, more particularly in their earlier work, and when they made a survey of the diets given to the rats in which these stones were found at necropsy, they were able to make the following generalisation: "In every instance where calculi developed the animals were without an adequate source of the fat-soluble vitamin for some time." They also noted that in their earlier work they had often used diets which were deficient in fat-soluble vitamin, whereas later this deficiency had not been permitted. Two recent papers on the subject agree in confirming Osborne and Mendel's observations. From the Imperial State Institute for Nutrition at Tokyo, directed by Dr. Tadasu Saiki, comes a paper by Yoshitomo Fujimaki,[2] in which deficiencies in the vitamins A, B, and C or in combinations of them, in the minerals calcium and phosphorus, and in protein, are examined as possible causal factors in stone in the bladder of rats. As a result of his investigations Fujimaki found that a deficiency in vitamin A regularly produced calculi not only in the bladder but also in the kidney and gall-bladder. The first did not develop consistently until the rats had been on the diet for 12 weeks or more; renal stones took a longer time and gall-stones longer still. The

[1] Jour. Amer. Med. Assoc., 1917, lxix., 32.
[2] Progress of the Science of Nutrition in Japan. By Tadasu Saiki. League of Nations Health Organisation. 1926. (Obtainable from Messrs. Constable and Co., London.)

rats were kept alive for these long periods by being occasionally given a normal diet for a short time; the principal difference lay in an addition of cod-liver oil. Fujimaki points out that the change from the deficient diet to the one containing cod-liver oil was accompanied by a change in the reaction of the urine from alkaline to acid. He was actually able to demonstrate that stones, detected by X ray, disappeared after the rat had received a course of cod-liver oil. Lieut.-Colonel R. McCarrison [3] has obtained very similar results. The diet he used was different and probably deficient in more factors than was Fujimaki's. He found that stone in the bladder had not developed in rats killed after eight weeks, but only in those which had been given the diet for a longer time. In this diet, relative poverty in vitamin A was only one of the defects which he recognised, lack of good protein, and an excess of phosphates being others. From these three pieces of work it seems fairly safe to conclude that a long-continued deficiency or partial deficiency in fat-soluble vitamins is an important ætiological factor in stone in the bladder of rats. It is rather surprising, however, to find that vitamin A is spoken of throughout as if it were the only fat-soluble vitamin; in all the experiments vitamin D was just as deficient, but this deficiency is never mentioned in discussing the ætiology. In 1917, when Osborne and Mendel wrote their paper, these two vitamins were not differentiated, but no reason is apparent in the work of Fujimaki or McCarrison (carried out in 1926) why a deficiency or an addition of vitamins A and D should be spoken of as an addition or a deficiency of vitamin A only, nor why the whole effect observed is ascribed to this vitamin. Possibly it is the only factor concerned; its absence is believed to lower immunity, and if the deposition of phosphatic calculi is regarded as of infective origin the modus operandi of the vitamin becomes intelligible. But there is certainly no definite proof of the supposition in any of the work described here.

GROUP MEDICINE IN PRACTICE.

IN this country coördinated work in medical practice is still in the experimental stage, and thus far, clinics have almost always been modelled on American lines. That is to say, that one person—in each case a physician—has acted as head of a number of regional specialists of whose work he is the ultimate arbiter. The objection to this method lies in the fact that the fate of the patient is at the discretion of an individual who retains the power of rejection of any evidence submitted by technical subordinates, should such evidence clash with his own preconceptions. Success in practice is mainly due to two factors, a theoretical knowledge of disease and the ability to make a diagnosis by a process of deduction from the heterogeneous symptoms displayed by a given patient. In proportion to the allegiance which the physician owes to the one or the other factor will he belong to the category of those who by excess of erudition never enunciate a finite opinion, or of those who, trusting too much to imagination, become the prey of obsessions. In other words, success is the reward of caution in avoiding pitfalls, or of occasional brilliance in diagnosis or treatment sufficient to overshadow failures. Group medicine alone offers the patient an escape from the Scylla of excessive caution and the Charybdis of dogmatism. In genuine group practice each opinion contributing to a diagnosis is primus inter pares, adduced at a round-table conference to which the patient's own doctor is invited. Each opinion is weighed in conjunction with all the others and a majority diagnosis based on established facts results. It is obvious that if opinions are to carry weight at a round-table conference they must emanate from men of recognised authority, and hence the number of groups working on these idealistic lines has economic limits. Further, to maintain the independence of such opinions group work should be an addition to the private and hospital practice of the members composing the group. If confined to diagnosis only, group work can hardly be a paying proposition because the public could not afford fees commensurate with the time and labour involved. Beds and treatment fees are essential to make the venture economically sound. There is, however, an objection to group work which is not commonly emphasised, and yet lies at the root of many of its difficulties. Successful group work demands group temperament. In the current number of the *Boston Medical and Surgical Journal* Dr. P. E. Truesdale surveys the subject of group medicine and sums up in its favour. He recognises this factor of temperament when he says, "group practice is essentially a young man's enterprise," and again "the original personnel of a group should be friends possessing a bond of sympathy and stable companionship; their interests, aims, and ideals should be identical . . . . They should be willing to subordinate individuality and make sacrifices for their common purpose; they should be charitable towards their co-workers, whose faults are inevitably exposed more often than when practising alone." In short, the group temperament may be best defined by that essentially British expression "sporting," and it seems that the most successful group will be composed of those whose past education has included some form of team games. Whatever may be said in detraction of athletics, it does cultivate two essentials to group practice, a sense of humour and level judgment. The administrator of a group should not merely be a man of all-round medical attainment but should have had some experience of leadership—Dr. Truesdale would have him a past athletic leader with, if possible, the training of a barrister. A barrister with a medical education might, indeed, be the ideal pilot if only for the reason that a barrister's training involves the marshalling of facts to the exclusion of fancies, but in visualizing the ideal chairman of a clinical committee we must not insist on so much equipment that no candidates will appear fit for the post.

DIATHERMY IN THE TREATMENT OF DEAFNESS.

BELIEVING that about 90 per cent. of deafness is caused by obstruction of the Eustachian tube, Dr. Maurice Coelst,[1] of Brussels, has devised a method of treating these strictures by the topical application of a high-frequency current in the form of diathermo-coagulation, which is the form of diathermy ordinarily used for surgical purposes. As a preliminary, the pharyngeal orifice is examined with the salpingoscope and the length and diameter of the stenosis is ascertained by the passage of bougies. A Eustachian catheter of insulating material is necessary—the author employs one made of ebonite—and a bougie of spring-steel about 0·3 mm. in diameter tipped with a small button of solder. The nose and Eustachian orifice are anæsthetised by applications of stovaine-adrenalin solution, and the indifferent electrode is applied to the lower part of the corresponding ear. The steel bougie is passed through the stricture and a current of 350 milliampères is turned on; after 3 seconds the bougie is slowly withdrawn through the stenosed portion of the tube during a further 6 or 7 seconds, after which the current is turned off. The ensuing reaction makes the patient deafer for a fortnight, after which he should have a further catheterisation. Dr. Coelst says that the characteristics of the cicatricial tissue resulting from diathermy are suppleness, absence of retraction, and lack of any tendency to produce granulations or adhesions. He has treated 15 cases by this method in all of which there had been no benefit from other forms of treatment. Two of the patients were lost sight of; but in all the remaining 13 the patency of the Eustachian tube was re-established, this being confirmed after six months in seven of them, and

[1] Bruxelles-Médical, July 3rd.

after a shorter time in the remaining six. In 11 cases there was a very marked improvement of hearing, and Dr. Coelst claims that none was made worse; vertigo disappeared in one case and tinnitus ceased in three cases. Although all aurists will not agree that Eustachian obstruction is the cause of 90 per cent. of deafness, it is at any rate a fruitful source of this affection. If this method can be shown, on a larger number of patients and with a greater lapse of time, to cure Eustachian strictures and to be reasonably free from danger, a considerable advance will have been made in the treatment of a very common and distressing disability.

PEPTONE INJECTIONS IN THE TREATMENT OF MIGRAINE.

THE possibility of migraine being due to protein supersensitiveness has frequently been suggested, and cases often occur in families in which asthma, urticaria, and other diseases of this class are common, although migraine itself is such a widespread disease that statistical conclusions tend to be fallacious. In the current number of the *American Journal of the Medical Sciences*, Dr. F. E. Ball, of Chicago, gives an account of the results of treatment in 20 cases. These cases were selected in so far as all of them had proved resistant to the commoner forms of treatment, such as regulation of diet and administration of iodine. The technique followed was to give an initial dose of ℥v. of 5 per cent. solution of peptone intravenously, followed after three or four doses by further injections in which the dose was increased by ℥v. each time until a maximum of ℥xxv. was reached. If no benefit followed a series of eight to ten injections the treatment was discontinued and regarded as a failure. When, however, the result was favourable, the time-interval between injections was gradually lengthened until the longest interval was found that secured freedom from headache, the injections being continued accordingly. The result in this series was that 50 per cent. of the cases were failures, seven cases (35 per cent.) were markedly improved, and three (15 per cent.) somewhat improved. When it is remembered that care was taken in the first place to select resistant cases these results must be considered as satisfactory. Dr. Ball was unable to discover any clinical or ætiological signs indicating which patients might be expected to receive benefit; but in all the patients who got marked relief visual disturbances which normally preceded the headaches continued at the time, though the full attack failed to mature. In the same paper the writer considers what association, if any, there may be between migraine, asthma, hay fever, urticaria, epilepsy, and eczema, but upon careful analysis of 1000 unselected family histories he is unable to find figures bearing out the common conception of a close relationship between these diseases, with the exception always of an association between hay fever and asthma.

MEDICAL PRACTITIONERS AND FELDSHERS IN LITHUANIA.

THERE are at present in Lithuania 476 properly registered doctors of medicine, 276 dentists, 353 feldshers, 270 midwives, 152 sisters of mercy, and 8 masseur specialists. There are also, we learn from the Northern News Service, 48 hospitals, with 756 beds, and three sanatoriums—viz., at Varena, Birstonas, and Kulatovoja. With a population estimated at about 2,000,000, it will be seen that there is, approximately, one registered doctor to every 4000 persons, one dentist to every 7000, one feldsher to every 6000, and one hospital bed to every 2300. By way of comparison it may be mentioned that in the British Isles, taking the population as well under 50,000,000, there are about 50,000 registered medical practitioners (including, of course, a proportion not in practice) and 15,000 dentists now on the Dental Register. The proportion of hospital beds to the population is locally so capricious as to make an average figure misleading. In this country we have nothing corresponding to the "feldsher." Lithuania has, no doubt, inherited this form of semi-qualified practitioner from the Russian Empire of which it was formerly a part. The origin of the feldsher system is of interest. In Peter the Great's Medical School in Moscow the most severe punishment for an erring student was expulsion from the school to serve in the ranks of the army. A less drastic punishment—reserved especially for students who repeatedly failed in their examinations—was to send them to serve, not in the ranks, but as barbers and blood-letters to the regiments. A little later a second category of military feldsher was created; a number of the sons of soldiers were trained in the arts of blood-letting and of nursing generally, and these helped to relieve the students by whom at that time the nursing in the military hospitals was mostly done. It was only after the emancipation of the serfs in 1861 and the creation of the system of *zemstvo* government that a class of civilian feldshers came into existence. Before the war they played an important part in the Russian medical system. There were large areas where no qualified doctor was to be found, and where the people were wholly dependent on the services of the feldsher. The system was no doubt a far from ideal one, but it was perhaps the best attainable under the conditions that prevailed. The feldsher's training was far from negligible, and his services were undoubtedly preferable to those of the "wise man" or "wise woman" of the village, to whom alone the peasant could otherwise have recourse. The whole question of "feldsherism" was described and discussed at great length by Dr. F. G. Clemow in THE LANCET [1] at the time of the International Medical Congress held in Moscow in 1897. Whether the system still prevails in Russia we are not in a position to state. In Lithuania, it would seem, there are approximately three feldshers to every four registered practitioners.

THE ÆTIOLOGY OF ERYTHEMA NODOSUM.

THOUGH the evidence of the last few years seems mainly to be in favour of regarding erythema nodosum as an expression of tuberculosis, nevertheless arguments are still being advanced in support of the hypothesis that it is produced by the organism or organisms responsible for rheumatism in childhood. Of the three rheumatic affections—acute polyarthritis, chorea minor, and acute endocarditis—the first is apparently the one most often correlated with erythema nodosum, and in many accounts of this condition attention has been drawn to the coincidence of pain or swelling in the joints of the affected limbs. An examination of the relationship was therefore undertaken by Dr. Albin Landau,[2] at Dr. Wallgren's Children's Hospital in Gothenburg, and at this hospital in the period Jan. 1st, 1922, to Sept. 1st, 1926, records were kept of all the cases of erythema nodosum on the one hand, and of acute rheumatic polyarthritis, acute endocarditis, and chorea minor on the other. On the record-sheets a special place was allotted to erythema nodosum, so that if there was a history of this complaint it would not be overlooked. It was found that among the 130 cases of erythema nodosum treated in this period there was only one in which the relatives could give a history of rheumatism. Among the 136 cases of rheumatism belonging to one or other of the three rheumatic categories mentioned above, there were four in which a history of erythema nodosum could be obtained. In all five cases in which the patients had suffered from both complaints the Pirquet reaction was positive, and in as many as three of these cases there were signs of pulmonary disease of a tuberculous character. Considering how common both erythema and rheumatic affections are in childhood, the fact that there was a history of

[1] Medicine Past and Present in Russia, supplement to the LANCET, August 7th, 1897.
[2] Acta Pædiatrica, 1927, vi., Fasc. 3–4.

erythema nodosum in about 3 per cent. of all the rheumatic cases can hardly be considered evidence of an ætiological relationship. In support of this negative conclusion may be added the interesting observation that the age-incidence of the two diseases was not identical; erythema nodosum began to appear after the age of 2 years and was commonest between the ages of 3 and 10, whereas the rheumatic complaints did not become frequent till after the sixth year. Nor was the seasonal prevalence altogether the same, for the rheumatic complaints were seen most often in the winter (especially January) and spring, whilst erythema nodosum was commonest in the spring (especially May). No definite conclusion, of course, can be based on this small series of cases, but the problem is interesting, and further attention might well be given to it.

AN ENDOWED RESEARCH INSTITUTE.

THE new pathological laboratory and research institute at the City of London Hospital for Diseases of Heart and Lungs, Victoria Park, the gift of the Prudential Assurance Company, was opened on July 19th by Mr. Neville Chamberlain, Minister of Health. Sir Alexander Kaye Butterworth, Chairman of the hospital, in acknowledging the generous gift of the Prudential, announced that the necessary additional cost of equipping and fitting out the laboratories had been partially met by an anonymous donation of £500 and by a contribution of £400 from the Ladies' Association. He was further desirous of building up an endowment fund for research, and a start had been made by a gift of £250. Mr. A. C. Thompson, the Chairman of the Prudential, in welcoming the Minister, mentioned that his company had decided to provide the remainder of the money necessary for equipment, a further sum of £400. Mr. Chamberlain said that no Government department was engaged in such an unceasing warfare as was the Ministry of Health. In this battle against disease he realised the extraordinary extent to which the public was served by voluntary efforts and by the sacrifice of individual citizens and groups of citizens. Pulmonary tuberculosis, heart disease, and diseases of the respiratory system were three of the first five diseases in order of deadliness. In the last ten years the mortality-rate of pulmonary tuberculosis had been reduced by nearly 28 per cent., that of respiratory disease by 34 per cent., and of heart disease by 3 per cent. From a national point of view, over 2½ million pounds was spent annually out of the rates and taxes upon the treatment of civilian cases of tuberculosis alone, and in considering the national loss a great deal had to be added to that figure for the waste of productive power and disablement. There were two directions in which he hoped it might be possible still further to reduce this drain upon the national resources—viz. (1) the improvement of the means of diagnosis, particularly perhaps in cancer and tuberculosis; (2) the provision of post-graduate education which would enable the general practitioner to keep up to date. He welcomed the recognition by one of the great companies connected with the National Insurance schemes of the necessity for looking ahead and making provision for work which would ultimately be for the benefit of the country as a whole. After the opening ceremony a garden party took place at which Lady Maud Carnegie was hostess, and the new laboratories were opened to visitors.

EPIDEMIC CATARRHAL JAUNDICE.

IT has long been recognised that the mild type of jaundice occurring especially in children and young adults tends to become epidemic from time to time. Its low mortality and the relative safety with which the disease can be treated in the general wards of hospitals have perhaps led to under-emphasis of its true infective nature; but most practitioners, and particularly those engaged in charge of schools and institutions where young people live in close contact, have from time to time observed outbreaks involving a number of cases. The Ministry of Health has just issued a report [1] on the subject by Dr. M. T. Morgan, of the Ministry, and Dr. H. C. Brown, of the Wellcome Bureau of Scientific Research. Their work deals with an outbreak of jaundice which occurred in a number of villages simultaneously in the Midland and Eastern Counties of England during the winter of 1925; more than 200 persons were affected, most of whom were young children, and except in two cases the course of the disease was mild and without serious consequences or sequelæ. Only one patient died, and it is perhaps worth remarking that in this case the clinical phenomena were somewhat atypical in that the illness was very severe from the beginning and was unaccompanied by pyrexia; the post-mortem appearances were those of acute hepatic atrophy, and there was a notable absence of pathological changes in any organs besides the liver. The importance of the other case which is recorded as serious is perhaps over-emphasised in the report as the child was well within a month of the onset of the disease. In general it may be said that the clinical features of this epidemic were those familiar to all medical men under the name of catarrhal jaundice. Owing to the obviously infectious nature of the malady special pains were taken to exclude the possibility that *Leptospira icterohæmorrhagiæ* was the cause of the disease, but inoculations of blood and urine into animals were uniformly unsuccessful in producing lesions characteristic of spirochætosis icterohæmorrhagica, and these experiments were so carefully controlled by different observers that it may be accepted as proved that the infection was not of this nature. In 1924 G. L. Gulland and George Buchanan [2] reported a small epidemic of spirochætal jaundice in East Lothian, but that appears to be almost the sole instance of an epidemic of the kind in Great Britain. In the August number of the *Edinburgh Medical Journal* T. J. Mackie and D. G. S. McLachlan record an outbreak of jaundice of exceedingly mild type occurring in five children attending an Ayrshire school, two adult members of one of the families also being affected. Spirochætes similar to atypical leptospiras were found in the urine of three of the four cases examined, but animal tests were negative, a result ascribed by the authors to devitalisation of the infecting organism by the acid and bile-containing urine. No information was obtained regarding the initial source of infection in this outbreak. Investigation into the causation of the milder form of epidemic jaundice is continuing, and it is to be hoped that the present report of the Ministry is preliminary. What is clear, even now, is that the conception of this disease as being due to a temporary blockage of the common bile-duct by a plug of inflammatory exudate is supported neither by clinical nor by laboratory evidence. Perhaps the most useful lesson which has been learned from the study of the van den Bergh and other tests of hepatic function is that cases of so-called catarrhal jaundice are invariably associated with the true hepatitis. The Ministry's report furnishes additional evidence in this direction.

EPSOM COLLEGE.

THE seventy-fourth anniversary of Founder's Day was celebrated at Epsom College last Saturday, when H.R.H. Prince Arthur of Connaught gave away the prizes, addressed the boys, and afterwards opened the new pavilion. To the casual observer, school speech-days bear a remarkable similarity year after year. There were, however, several reasons why those responsible for the welfare of Epsom could regard this particular anniversary as a mile-stone on the road of progress. In the first place, the presence of Prince Arthur showed a continuation of the interest that the Royal Family has always

[1] Reports on Public Health and Medical Subjects, No. 42. H.M. Stationery Office. 9*d*.
[2] Brit. Med. Jour., 1924, i., 313.

displayed in the school. Secondly, this present year has seen the completion of the penultimate stage in the council's plans for the advancement of the school, whereby it takes its place among those with a muster roll of 400. Yet another event of importance, especially to the boys themselves, was the opening of the new pavilion, while the presence of a large number of old boys among the thousand guests was a pleasant indication of their interest and support. Prince Arthur divided his address, which was essentially for the boys, into two parts: the fine part in life to be played for the welfare of the community by those of them who were destined to become doctors, and the great opportunity offered by emigration to those who had not yet chosen their career. From his own personal experience of South Africa, he could assure them that successful careers could be made in the Dominions and Colonies by public school boys of the right stamp possessed of grit and a capital of £1000 to £1500, who were prepared to take up agriculture. When Dr. Raymond Crawfurd became chairman of the council some five years ago certain plans were formulated, which aimed at the increase in numbers of the boys of public school age from 250 to 400. To achieve this has necessitated an expenditure of over £40,000 in bricks and mortar, but the result is that there are now 387 boys, who have a beautiful chapel, up-to-date chemistry and science classrooms, with many other amenities of public school life that were previously lacking. As regards the pavilion, it is worthy of note that less than a year ago old boys and parents were first asked to subscribe. Within six months, in spite of the general strike and the ensuing coal strike, £2700 had been raised, and within another six months the pavilion had been built. It provides accommodation of modern type in the way of washing, changing, and dining-rooms, seating accommodation for all the college needs for years to come, a "tuck shop," and premises for the ground staff's accommodation. Messrs. C. E. Barry and Son, the architects, presented the design as a donation to the Pavilion Fund, Mr. Barry, junior, being himself an old boy. The headmaster (Mr. A. C. Powell), in his annual report, spoke of a very satisfactory position in school life. Chief among the successes was the senior open science scholarship at Jesus College, Cambridge, won by E. A. Marsh, who achieved the unusual by passing the B.Sc. examination of London University while still at school. As a result of bequests, two new entrance scholarships, one of £120 per annum and one of 100 guineas per annum, will be made available for open competition.

A MEETING OF NEUROLOGISTS.

THE American Neurological Association several months ago accepted an invitation from the Neurological Section of the Royal Society of Medicine to hold its annual conference this year in London, and to have a series of joint meetings with English neurologists. Thirty-four of the visitors, many of them accompanied by their wives and daughters, arrived in this country on Friday of last week, whilst others were already in this country. The proceedings began on Monday evening with the reception of the visitors at the Royal Society of Medicine. Sir James Berry (President of the Society) and Lady Berry received the guests in the library, and there was a large attendance both of visitors and Fellows. Among the former were Dr. Charles Dana (President of the American Neurological Association), Dr. F. Tilney, Dr. H. A. Riley, Dr. B. Sachs, Mr. Penfield, Dr. Cornwall, Dr. N. W. Winkelman, and Dr. I. H. Weisenburg (Secretary of the Association). After the reception Sir James Purves-Stewart, this year's President of the Neurological Section of the Royal Society of Medicine, gave a lecture entitled "Mount Athos," in which he described his visit in 1916 to that remarkable community, and showed many lantern slides of its monasteries. He explained the organisation of the monastic republic, and the exclusion from it of every female, human or animal—"no cows, no milk, no hens, no eggs." The architecture of the monasteries, many of which date from the tenth century, was illustrated, and some account was given of life within the walls. The lecturer was impressed by the mental stagnation within the community, and the lack of appreciation of the priceless manuscripts which are in their possession. Dr. Charles Dana afterwards proposed a vote of thanks to Sir James Purves-Stewart for his entertaining lecture; this was seconded by Dr. Bernard Sachs, and conveyed to the lecturer by Sir James Berry. The joint meetings of the Association and the Section were continued during the week, and a report of the early proceedings appears on p. 258.

WE regret to announce the death on July 26th in London, in his 83rd year, of Sir Bryan Donkin, consulting physician to the Westminster Hospital. A leading criminologist, his outspoken expressions have been of the greatest public value in many social circumstances. A fuller obituary notice will appear in our pages.

MEMBERS of the medical profession will also learn with sorrow the death, in his 66th year, of Mr. Alfred C. Taylor, of Peterborough, whose radiological work commenced with Rontgen's discovery and was carried on assiduously for over 30 years in spite of the serious consequences to his health manifested in dermatitis and the loss of fingers from both hands.

THE conferment of a knighthood upon Dr. Wilfred Thomason Grenfell, C.M.G., will give pleasure to his many friends inside and outside the medical profession. Dr. Grenfell is a Fellow of the Royal College of Surgeons of England, who holds honorary degrees of the Universities of Oxford, Harvard, and Williams. As doctor, missionary, and mariner his name will always be associated with life and progress in Labrador.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCXXXIV.

THE TREATMENT OF ERYTHEMA MULTIFORME AND ALLIED ERUPTIONS.

THIS large and relatively common group of toxic erythematous eruptions will for our purposes include erythema multiforme (e.g., iris or target forms), erythema nodosum or contusiforme, and purpura.

A simultaneous consideration of these clinical types is justified by what has been termed their rheumatoid characters. The lesions are always evanescent or fleeting, tending to recur, sometimes with seasonal variations, and not infrequently accompanied by fever, constitutional disturbances, and vague rheumatic pains around the joints and in fibrous planes. Scarring is never produced in uncomplicated cases. A certain similarity in the pathological histology further justifies this grouping. Exudation of serum or blood through a damaged capillary endothelium is the keynote. In all three conditions there is some evidence to support the view that a hæmolytic streptococcus may play a part in the causation. It has actually been recovered and grown in pure culture from some of the lesions, especially those of a purpuric type. In a large percentage of the cases there is a history of tonsillar trouble, and it is likely that the organisms or their toxins may enter the circulation at this point. In others, again, there is pronounced dental sepsis, which may be obvious or revealed only by X rays. The possibility of these two sources of blood infection should always receive due consideration, but it has to be admitted that eradication of such foci does not invariably lead to a cure or prevent relapses.

If we are satisfied that the surgical work has been thorough, and that the macroscopic and accessible foci have been completely eradicated, we are then faced with the more difficult and problematical search for subsidiary foci, a task which may baffle even the most experienced. In this connexion it is well to remember that the causative toxin may be medicinal or metabolic, as well as bacterial, and that cases are recorded which appear to have followed the ingestion of tinned foods; this brings the clinical picture into line with those (like urticaria) for which an anaphylactic explanation is put forward. In urticaria there is considerable experimental and clinical evidence that histamine, or a chemical substance resembling it, is the actual causative agent. By analogy there is much to be said for the theory that the introduction of certain drugs—e.g., iodine or quinine—in predisposed persons, the existence of septic and occluded foci, or the ingestion of stale foods, may lead to the formation or splitting off from tissue molecules of a definite type of albuminoid poison which specifically produces the eruptions we call erythema multiforme, erythema nodosum, or purpura. Such a hypothesis is attractive, and whether ultimately proven or not, at any rate provides a basis for treatment.

There are special therapeutic indications in each of the three members of the group.

Erythema Multiforme.

In the acute case the treatment should at first be symptomatic only, for it is never wise to attack even obvious foci surgically when the whole circulation is presumably flooded with the causative virus. This caution would seem especially advisable in cases with oral or pharyngeal lesions. These patients are best treated in bed, with the usual attention to diet, purgation, &c. If gastro-intestinal symptoms occur, calomel, salol, or high rectal washouts with saline or weak permanganate of potash (1 in 5000 or weaker) may be administered. If there is much oral sepsis or eruption of bullæ, with rapid formation of eroded or ulcerated areas in the mouth, only the bland and soothing antiseptics will be tolerated. These include weak solutions of glycothymolin (℥ i. to O i.), peroxide (5 vols. per cent.), and bicarbonate of soda (gr. x. ad ℥i). Pains in the joints should be treated with salicylate of soda, but do not respond so well as the true rheumatic cases. While the patient is under immediate medical supervision every effort should be made to discover the source of infection. Swabs may be taken from the tonsils or gums; a bacterial investigation of sterile samples of the urine may prove useful for the purposes of diagnosis, or for the preparation of a vaccine at a later stage.

Local treatment of the cutaneous manifestations is a simple matter, for the patient, as a rule, does not complain of much more than burning or slight itching. Lead and calamine lotion in equal parts usually suffices to give relief. Strong antiseptics should never be used, and lotions and powders are better than ointments.

Vaccine treatment is best deferred until the surgical procedures are completed. In one case, in which a virulent hæmolytic streptococcus had been recovered from the urine, the fæces, and the apical abscesses at the roots of many teeth, every injection of the autogenous vaccine was followed on the next day by a fresh eruption of vesicular erythema multiforme over the whole trunk. The phenomenon showed how sensitive some patients are to the virus, and suggests the need for caution in the matter of dosage and dose intervals. There is good reason to suppose that in the case quoted the vaccine helped to promote the recovery of the patient.

Erythema Nodosum.

In this disease the inflammatory process and the exudation of serum are at a deeper plane, and occur in tissues, such as the shins, in which pressure effects give rise to pain. Pain is indeed usually the symptom that most urgently requires treatment. Bed is essential, and salicylate of soda or aspirin gives considerable relief. The affected members may be wrapped in cotton-wool over a 10 per cent. ichthyol ointment, or lead compresses may be applied. While most authorities are convinced of the presence of circulating toxins in such cases, there is some doubt as to their nature. The safest position is to regard erythema nodosum as a symptom which may occur as a manifestation of various poisons, and that in its ætiology rheumatism, tuberculosis, streptococcal infections, certain acute specific fevers, and gastro-intestinal toxæmia may play a part. During the attack the same general measures are applicable as for erythema multiforme; when the attack is over there should be instituted a similar process of investigation, which must include an examination of the patient's personal and family history, especially as regards tuberculosis.

Purpuric Eruptions.

Purpuric eruptions may be classified broadly into primary or idiopathic, and secondary. The ætiology of the former group is entirely unknown, and its incidence increasingly rare. There is ground for the belief that in the future a bacterial or biochemical cause will be found for all cases. A blood count and a Wassermann test should precede all other investigations, for purpuric eruptions may occur in many blood diseases of both known and unknown causation. They may also occur in diabetes and advanced renal disease, and are of grave significance when associated with intermittent fever and signs of organic disease of the heart. Beyond attention to the points already laid down above, little can be suggested on general lines. The treatment must in the main be symptomatic and governed by the severity of the case. When hæmorrhage from mucous membranes, from the kidney, or from the stomach is a feature, the outlook is serious, and it has been computed that 14 per cent. of such cases proceed to a fatal termination. Three varieties of idiopathic purpura are described.

(1) *P. simplex*, usually seen in young children as small petechial spots on the legs chiefly. There may also be joint pains and slight fever. Rest in bed and a light diet is usually all that is required, and recovery is the rule in from two to three weeks.

(2) *P. rheumatica.*—In this type the joint symptoms predominate, but occasionally there is an associated eruption of bluish red macules.

(3) *P. hæmorrhagica.*—As its name implies, the hæmorrhages, which may be either cutaneous, subcutaneous, or general from any mucous surface, are the main feature of the clinical picture. Joint symptoms may also occur, and treatment by salicylates may afford some relief.

The number of recommendations available for the treatment of severe cases of purpura is in inverse ratio to the degree of their reliability. Adrenalin chloride by the mouth or by subcutaneous injection of 5 to 10 minims of a 1 in 1000 solution three to four times daily is probably the most valuable symptomatic agent we possess. In desperate cases blood transfusions from a relative in the corresponding blood group may be tried, while in those less dangerously situated the blood may be given intramuscularly in 20 c.cm. doses in the buttocks. Horse serum (20 c.cm.) at intervals of three or four days has other advocates, but if used must be given with due care to the avoidance of the most troublesome and ever-present possibility of subsequent serum disease.

Calcium salts are generally prescribed for all cases of purpura, and in the severe types with serious hæmorrhages intramuscular injections of whole blood are said to have been beneficial. In cases of a chronic relapsing type, X ray irradiation of the spleen, which is sometimes felt to be enlarged, may do good, and recovery has been reported after splenectomy.

In the secondary group of purpura every effort must be made to trace out and eradicate a septic focus, for, just as in erythema multiforme and erythema nodosum, the best results can only be expected by discovery and abolition of the cause.

ACUTE RHEUMATISM IN CHILDHOOD.

REPORT BY THE MINISTRY OF HEALTH.

THE bacteriology, incidence, and institutional treatment of acute rheumatic infection are the subjects chiefly considered in the latest Report [1] of the Ministry of Health. Unlike that issued in 1924,[2] this Report deals with rheumatism in children, the disease being studied in its relation to cardiac disability. In his preface Sir George Newman points out that in England and Wales during 1926 diseases of the heart caused 142 out of every 1000 deaths—cancer causing 117 and tuberculosis 82—and attributes some 40 per cent. of the cardiac mortality to rheumatism. It is only, he says, by the early, continuous, and thorough treatment of this infection that we can hope to save lives or prevent crippling, and there is perhaps no more striking example of the principle that treatment must begin as soon as possible after a disease becomes manifest.

Bacteriology.

The first section of the Report is a historical survey, after which Dr. Arthur Eastwood summarises our knowledge of the bacteriology of acute rheumatism. Observers who have reported positive results have generally, he says, been in favour of some form of micrococcus, and most workers now agree that the cocci found in association with the disease do not from a species of their own but must be included within the group of streptococci. Some streptococci produce hæmolysis in a blood medium and are termed *S. hæmolyticus*. Others do not hæmolyse blood but form green colonies and are therefore known as *S. viridans*. The cocci found in acute rheumatism, though occasionally hæmolytic, are generally *S. viridans;* but organisms of this type are widely distributed, and are often found as harmless saprophytes or as the causal agent in lesions which have nothing to do with rheumatic fever. Attempts to distinguish the rheumatic organism from the others by serological reactions have not been conspicuously successful, and the strains associated with acute rheumatism do not appear amenable to grouping either into a single class or into a reasonably small number of types. It is possible that future work will bring some sort of order into the apparent chaos.

Another method of approach is experimental inoculation of animals, and from work of this kind Dr. Eastwood draws the important conclusion that the lesions produced in the rabbit by *S. viridans* isolated from cases of rheumatic fever are not clearly distinguishable from lesions produced in the rabbit by streptococci from other sources. While refusing to adjudicate between the positive and negative findings of the many workers who have tried to isolate organisms from the blood or organs of rheumatic patients, he points out that negative results may be due either to absence of *S. viridans* as an infecting agent or to its low viability when it gains access to the blood in small numbers. Further work on blood cultures is of primary importance. There are two main objections to the theory that streptococci are merely secondary invaders in acute rheumatism and that the true causal agent is a filter-passer. These are: (1) that there has been no satisfactory demonstration of an ultra-microscopic virus, and (2) that diseases thought to be due to viruses of this kind are generally highly infectious.

In conclusion, Dr. Eastwood remarks that many experienced observers think that acute rheumatism is caused by *S. viridans*, and although they have not proved their case completely they have good reason for asserting that no rival theory has made substantial headway. From the bacteriological standpoint interest appears to be mainly focused on further analysis of this group of organisms by biochemical and immunological methods, though the theory of an ultra-microscopic virus cannot be absolutely excluded.

Predisposing Causes.

Part II. of the Report considers the incidence and prevention of diseases of the heart. The cardiac mortality, it is claimed, is increasing despite an apparent charge in the nature of the rheumatic infection. Acute rheumatism is less acute and virulent than it was 40 or 50 years ago, but its minor manifestations appear more frequently than before. Urbanisation and industrialisation appear to be potent predisposing factors in the causation of cardiac disease, and receive full consideration in a recent report [3] of the Medical Research Council, which deals with heredity, environment, infectivity, housing, dampness of house and site, overcrowding, sore-throat, and other subjects. The Council's investigators found that the incidence of acute rheumatic infection amongst those in close contact with a patient was unduly high, suggesting that infection was transmissible by infected persons. It was observed that among the very poor and destitute rheumatism is less common than among the children of the hospital class, but Sir George Newman throws doubt on this observation, and an investigation described in the Ministry's Report suggests that the poorer the home the greater the risk. The disease is, of course, rare among the well-to-do, and in reference to its absence at Eton College for many years it is pointed out that besides great advantages in nurture a large proportion of boys entering the College (nearly 70 per cent. in a recent sample) have had their tonsils removed.

Nature of the Disease.

No satisfactory definition can yet be given.

"Probably (says the Report), it is correct to say that acute rheumatism is a general systemic infection, comparable in many ways to the infection of tubercle or of syphilis, 'A chronic slowly progressive disease characterised by intervals of calm simulating complete recovery and periods of activity which entail further damage to the organism' (T. T. Mackie) that this infection usually enters the system through infected tonsils, that up to the age of puberty the brunt of the infection usually falls upon and abides in the heart, and that just before and at puberty, especially in the female child, there is a special liability of the central nervous system to infection. After puberty the brunt of infection tends gradually to fall rather less upon the heart and rather more upon the synovial membrane of the joints, although the heart is still affected in more than half even of adult patients. . . The prodromal signs of the rheumatic infection in children are often pallor, loss of weight, slight daily rise of temperature, accompanied by an increased pulse-rate, and fatigue out of all proportion to the task or play. To distinguish what is called the pre-rheumatic child from the equally indefinite pre-tubercular child is difficult. Both require the most careful medical supervision, and the so-called pre-rheumatic child is too often in reality already the rheumatic child."

The early recognition of rheumatic infection is as difficult as it is important. The chief minor manifestations, which are often the first to appear, are growing pains, recurrent tonsillitis, and subcutaneous nodules, whilst other premonitory manifestations include epistaxis, erythema multiforme, persistent headache unexplained by eyestrain, and nervous symptoms which may be signs of so-called latent chorea—e.g., nightmare, talking or doing sums during sleep, habit spasms, acquired enuresis, "exaggerated" fidgetiness, clumsiness, and deterioration of handwriting.

[1] Reports on Public Health and Medical Subjects, No. 44. 1927. H.M. Stationery Office. 1s. 6d.
[2] The same series, No. 23.

[3] Medical Research Council: Special Report No. 114. 1927. H.M. Stationery Office. 2s. 6d. (See THE LANCET, 1927, i., 552 and 562.)

Growing Pains may be mild and evanescent. They are usually described as most noticeable in the hamstrings behind the knee, but H. P. Newsholme found in 50 per cent. of his cases that pain was referred to the front of the thigh. Stiff neck in a child should be regarded with suspicion. Growing pains constitute the distance danger-signal of rheumatism, and may afford weeks or even months of warning. "When they are present in a child with signs suggestive of tonsillar disease it is indeed time to seek medical advice, and probably to enucleate the tonsils."

Recurrent Tonsillitis.—At routine examinations of elementary school-children at least 5 per cent. are found to have enlarged tonsils, whereas among children who have once shown the major signs of rheumatism the proportion is at least ten times as great. Recurrent tonsillitis is a danger-signal of acute rheumatism, and in about 10 per cent. of cases a sharp attack of tonsillitis is a prodromal symptom.

The major manifestations are, of course, arthritis, chorea, and carditis. The first occurs in 60 to 70 per cent. of all children with rheumatic infection sufficiently ill for admission to hospital. It is estimated that of the 5,000,000 children at ordinary elementary schools in England and Wales 0·7 per cent. have organic cardiac defects (0·5 per cent. requiring supervision and 0·2 per cent. requiring treatment).

Tonsillectomy.

Mackie [4] found that only 57 per cent. of first recurrences developed within four years of the first attack of rheumatic fever. The apparent success of tonsillectomy or other therapeutic or preventive measures must be reconsidered in the light of this conclusion.

The report sums up as follows: "The truth probably is that tonsillectomy (if practised early enough and if completely performed) is of great value not only as a prophylactic against a first attack of acute rheumatism, but also that it is often an effective preventive of recurrence, and that it also has a highly beneficial effect in preventing rheumatic carditis from resulting in permanent damage."

The fact that tonsillectomy often does not prevent a first attack of rheumatism is attributed, partly at least, to the infection having reached the cervical glands or some other focus before operation. "Even if this be so, however, the removal of infected tonsils is almost certain to prove beneficial, and examples of any harm following the operation are exceedingly rare."

In his preface Sir George Newman remarks that in its indications of the value of tonsillectomy the report may perhaps go further than the evidence warrants.

Care of Rheumatic Children.

Over 2000 children receive in-patient treatment in London every year, of whom more than half are treated at Poor-law infirmaries. The second report [5] of the British Medical Association's sub-committee stated :—

"The voluntary hospitals in general, and the children's hospitals in particular, make every effort to provide in-patient treatment for patients with active rheumatic symptoms, and their needs are fairly well met. Where enough accommodation is wanting it is usually a matter of either particularly heavy incidence or a general shortage of hospital beds for the district."

Mrs. Forest Smith, in a careful survey of the treatment given to the 508 rheumatic children below 12 years of age brought to St. Thomas's Hospital during a year, finds that 77·2 per cent. were treated as out-patients at home. Of these 508 children, 21·9 per cent. already had cardiac damage, and a further 21·3 per cent. had threatened cardiac involvement. She shows clearly the disadvantages of home treatment in the hospital classes, and in view of her data Sir George Newman regards the B.M.A. subcommittee's statement as too favourable. "For every child who is fortunate enough to be admitted as an in-patient there are," he says, "two, three, or even four children who need in-patient treatment, and who do not get it." These children cannot get the necessary rest and control in a crowded, busy, restless home.

The report concludes with a survey of treatment from the public health standpoint. The following principles are laid down :—

"Complete" rest should be continued for at least three weeks after (1) the pulse-rate and temperature have returned to normal, (2) anæmia has disappeared, and (3) the heart signs are unchanged. Under favourable conditions "graduated" rest may then be substituted. Country air, perfect environment, and constant medical and nursing supervision are required, together with special educational arrangements. Removal of focal sepsis is regarded as essential.

Detailed consideration is given to the care of rheumatic children at (*a*) special homes, (*b*) ordinary convalescent homes, (*c*) day open-air schools, (*d*) residential open-air schools, and (*e*) physically defective schools, and important suggestions are made as to the coördination of measures for prevention and treatment.

With the exception of the preface, and sections by Dr. Eastwood, Mrs. M. Forest Smith, and Dr. J. E. A. Underwood, the report is the work of Dr. J. Alison Glover, of the Ministry of Health.

The authors are to be congratulated on their presentation of facts and opinions.

MEDICINE AND THE LAW.

No Prescriptive Right to Pollute Rivers.

A CORRESPONDENT has drawn attention to a phrase in the article (THE LANCET, April 16th, p. 830) on the Pollution of Rivers, in which the words were used "plea of a prescriptive right to pollute." As he rightly points out, the defence of prescriptive right is greatly restricted, if not entirely abolished, by the decision of Mr. Justice Eve in 1922 in Hulley *v.* Silversprings Bleaching and Dyeing Co. The pollution of a river is a statutory offence under Section 4 of the Act of 1876, and no one can acquire a prescriptive right to do what a statute forbids. The effect of this case has already been explained in these columns (1926, ii., 715). As has often been remarked, the decision has hardly been given its proper effect. In these times, which are so critical for industry, magistrates and judges are, perhaps naturally, anxious not to hamper local commercial activities or to throw men out of employment. There is an atmosphere of toleration because public opinion has not been focused upon the evils of pollution. Prosecutions and actions for injunction thus lose some of their terror for those who are responsible for pollution. Thus, in turn, others are discouraged who else might institute proceedings. Meanwhile, if a recent speech of the Earl of Balfour in the House of Lords is to be taken as the official view, it would seem that the hopes of cleaner rivers are remote.

It will be worth while to elaborate the ruling given in Hulley's case (1922, 2 Ch. 268). Mr. Hulley owned Pool Bank Mill on a stream called Timbersbrook in Cheshire. He spent £5000 on altering the mill and fitting up machinery for his trade as a cotton doubler, and then found he could not begin business because the defendant company was interrupting his riparian right to a full flow of clean water. The company, after pleading the customary denials so as to put him to the proof of the facts, contended that, if there was any pollution, there was a long-established usage justifying it, either from time immemorial, or under

[4] Amer. Jour. of Med. Sci., August, 1926, p. 220.
[5] Brit. Med. Jour. (Supplement), April 16th, 1927.

a presumed lost grant or under a 20-year period of prescription. The law has always been kind to long-established usage. If the courts find that there has been such usage over a long period they are lenient in exacting proof of it. The law allows evidence of 20 years' usage to be prima facie conclusive, and the courts are endowed (as a judge has said) with great powers of imagination for the purpose of supporting ancient use—for example, they favour the fiction of a lost grant. But in Hulley's case Mr. Justice Eve was clear that the discharge of pollution into the Timbersbrook was an offence under the 1876 Act, that this offence had been continued right down to the trial of the action, and that a lost grant cannot be presumed if the grant would have been in contravention of a statute. "As title by prescription is founded upon the presumption of a grant, if no grant could lawfully have been made no presumption of the kind could arise." The claim to pollute was held to have failed, and the company had to pay the costs. This was not new law. The learned judge cited a case in which he had been engaged when still at the Bar (Neaverson *v.* Peterborough Rural Council, 1902, 1 Ch. 557) on a different subject, but laying down the same principle. There was a question of pasturage on roadsides in the fen district. An Act of Parliament limited the pasturing to sheep, doubtless to avoid the breaking-down of drainage banks by the trampling of horses and heavy cattle. For 50 years the highway surveyor had let the roadside herbage for the pasturing of horses and cattle as well as sheep. Cozens-Hardy J. was satisfied with this long-established usage as setting up a presumption of a lost grant. The Court of Appeal overruled him. Unless such an imaginary grant had a legal origin the court could not imagine its existence. The grant would have been contrary to the Act of Parliament and thus it was unimaginable. What was wanted to support the ancient usage was not a lost grant, but a lost Act of Parliament, and Acts of Parliament do not lose themselves. There are similar observations by Lord Macnaghten in a House of Lords case (Butterworth *v.* West Riding of Yorkshire Rivers Board, 1909, A.C. at p. 54). But indeed there is no doubt about the law. What is at fault is the half-hearted application of the existing powers of individuals and local authorities to prevent pollution. Prosecutions will have no deterrent effect till courts become aware that public opinion is aroused and insists upon the enforcement of the law.

DONATIONS AND BEQUESTS.—Mr. Thomas Alfred Harrop, of Timperley, Cheshire, and of Whitworth-street, Manchester, left £500 each to St. Mary's Hospital, Whitworth-street West, Manchester, the Manchester Royal Children's Hospital, Pendlebury, the Manchester Babies' Hospital, Levenshulme, and £250 to the Ancoats Hospital.—Mr. Abraham Ormerod, of Walsden, Todmorden, Yorks, after some annuities and legacies, left all his other property—about £30,000—for such charitable purposes or institutions or objects in England as his trustees in their uncontrolled discretion may select, but he expressed the wish (but without creating any trust in the matter) that they will have regard to such institutions and objects as will tend to alleviate pain and suffering, and in their opinion be of direct benefit to the people of Todmorden.—Mrs. Joseph Cunningham and her two sons and daughter have united in a gift to Noble's Isle of Man Hospital of an electro-medical pavilion with all modern equipment, estimated to cost between £5000 and £6000.—The record gift of £11,857 in subscriptions was announced at the festival dinner of the Royal Hospital and Home for Incurables, Putney, which was held on June 30th.—The late Mr. Solomon Kaufman, of Hartlepool Durham, left, among other bequests, £500 each to the Hartlepools Hospital and Dispensary and the Jews' Hospital and Orphan Asylum, West Norwood, S.E.—A cheque for £5000, to be used in extending accommodation, has been given to the Adamson Cottage Hospital, Cupar, by Mr. J. B. Crichton, of Luthrie Bank, North Fife.—The trustees of the late Mr. William Shepherd have made a second payment of £1000 to the General Lying-in Hospital, Lambeth, for the purpose of naming another bed to be called "The William Shepherd Bed."—Mr. Bernard Baron, of Hove, has given £5000 for the benefit of the crippled children of Chailey Heritage Schools, Sussex.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Opposition to Medical Appointments.

THE transfer of the selection of candidates for local offices from the local authorities to the local appointments commissioners has not worked without some friction. The machinery of making an appointment is as follows: When a vacancy occurs in the employment of a local authority, the latter, unless it chooses to fill the vacancy by transfer of an officer already in the public service, notifies the Minister of the existence of the vacancy. The Minister invites the local appointments commissioners to nominate a suitable candidate, and the local authority is bound to appoint the candidate so nominated. In their selection of a candidate in the case of medical vacancies the appointments commissioners always proceed on the advice of a selection board. This procedure was followed some weeks ago in the case of a dispensary vacancy in County Roscommon, and the name of a woman doctor was submitted to the county board of health for appointment. Protest was made by the board that the district was unsuitable for a woman doctor, and the Minister was asked to have another name submitted. He has remained obdurate, and he finally threatened to take the necessary legal proceedings to enforce the appointment of the lady nominated. In response to this the entire county board of health has resigned. It is of interest to recall that the legislation on which the present method of appointment is based was introduced in order to get away from the bribery and corruption which in some areas at least surrounded appointments made by the local authorities. This corruption was proved in regard to a member of the Roscommon board of health, who was sent to gaol for some months for soliciting a bribe in connexion with an election.

It is not, however, only in Roscommon that friction has arisen out of the new method of appointment. The Carlow County Council has refused to appoint the gentleman nominated by the appointments commissioners for the post of county medical officer of health, while an appointment in County Monaghan was only made after several months of controversy.

The Dentists Bill.

The Dentists Bill, reintroduced to the Dail three weeks ago, has been postponed and will not receive further consideration this session. This is perhaps just as well, as some points of importance are raised in the Bill, apparently without due consideration. It is understood that the Bill is the result of deliberations between representatives of the Government and of the dental profession, in which representatives of the medical profession had no part. The Bill proposes to prohibit the practice of dentistry or dental surgery by all who are not registered dentists. This prohibition makes an exception of medical practitioners on the register at the date of the passing of the Act, but only makes a partial exception of future medical practitioners, who may give dental treatment, advice, or attendance in "urgent dental cases." This interference with the rights and privileges possessed by the medical profession has roused opposition, and representations thereon have been made to the Government by the Council of the Royal College of Surgeons in Ireland. It is pointed out also that a curtailment of the practice of medicine and surgery, such as the Bill proposes, may give rise to some uneasiness as to the agreement recently arrived at between the British and Irish Governments on the subject of the Medical Register. It is hoped that the time given for further consideration may help to dissolve the difficulties raised by the Bill. One cannot but think that these difficulties would have been avoided altogether had the Government had the advantage of an earlier consultation with representatives of the medical profession.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Ponudos or Pseudo-leprosy.

WHILE on a visit from Guatemala, where he is stationed, Dr. Roblès has described to the Academy of Medicine a disease frequent enough in Guatemala, but which has never yet been classified. The lesions are chronic, resembling elephantiasis of the feet, the onset being insidious with successive remission and advance. The first sign is an erythematous patch accompanied by transient enlargement of the inguinal glands and high fever, followed by chronic œdema with thickening and pitting of the toe-nails and dorsal surface of the feet. The lesions only affect the soft parts, the skiagram showing the bones to remain unaffected. Dr. Roblès proposes the name of pseudo-leprosy for this affection, inasmuch as it has been frequently confused with true leprosy, although readily distinguished by the absence of lepra bacilli and of any alteration of sensation. On the other hand, it is distinguished from other kinds of elephantiasis by the absence from the blood and tissues of any recognisable parasites.

The Medico-legal Aspect of General Paralysis.

The favourable results of treatment by arsenical and bismuth salts, by shock therapy, and especially by malarial infection, in cases suspected of meningo-encephalitis or even at an early stage of general paresis, have materially altered the outlook for the patient. Figures show that the proportion of cases in which long remission is obtained varies from 30 to 40 per cent. Prof. Henri Claude, who has dealt with 143 cases at the clinic for mental diseases, gives a percentage of 40·5 of complete remission as compared with 10 to 12 per cent. of partial remission occurring spontaneously. This alteration in outlook has necessitated the revision of the legal measures taken for the protection of these patients. It is, of course, necessary to take account of the importance of their responsibilities and of the nature of their work, and in any case it is desirable in the patient's own interest for him to avoid overwork and remain an indefinite time under medical supervision. Prof. Claude counsels reserve even in the cases of most favourable aspect, when the question of civil capacity and the possibility of relapse has to be decided. Yet he admits that in a number of patients who were allowed to return to their occupation, progress has been continuous and satisfactory. It is therefore possible that medico-legal decisions in general paralysis may in the future not be couched in the stringent form of the past. The appointment of a provisional administrator may avoid the necessity of making any final decision and allow of watching the evolution of the disease when submitted to energetic treatment. On the other hand, in view of the unbalanced mentality of these patients, it would obviously not be judicious to allow them too rapidly to recover control of their affairs. Cases of complete restoration are still the exception, but in view of the increasing number of recoveries, Prof. Claude is right in insisting on caution in taking medico-legal decisions as to civil capacity.

Leprosy in Paris.

The Paris Municipal Council is considering measures for the control of leprosy, its action being urged because there is a tendency on the part of lepers from various countries to seek the treatment afforded by the Hôpital St. Louis and other Paris hospitals. The new measures contemplate isolation of the cases in a special ward at the Hôpital St. Louis, obligatory declaration, domiciliary control by therapeutic and bacteriological methods, exclusion of lepers from occupations such as hair-dressing, laundries, and the cooking and sale of foods, and the creation of leprosariums and the elaboration of arrangements with foreign countries with a view to restriction of the immigration of lepers into France.

VIENNA.

(FROM OUR OWN CORRESPONDENT).

Deaths in the Profession.

BY the death a few days ago of Prof. Rudolf Kaufmann, the cardiologist, Vienna loses an investigator of great ability. Whilst still a young man he commanded the attention of Nothnagel and Maunaberg by his work on the pathology of the intestinal canal, and when, at the beginning of this century, modern methods of research on the heart were made known, he threw himself with zeal and ardour into the new study; a long series of papers on the size of the heart, the cardiac muscle and its rhythm, stenocardia, pulmonary œdema, parasystole, allorhythmia, and the circulation in the coronary vessels show to what wide understanding he attained. Together with Prof. H. Mayer he experimented on the pharmacological side of his subject, and during the late war he organised a huge "heart hospital," in which the effects of shock, over-exertion, infectious disease, and neurasthenia on the normal and diseased heart were studied. Many soldiers regained their cardiac health in this hospital, and after the war Kaufmann succeeded in perpetuating its service for the benefit of the general public. His death at the age of 56 came quite unexpectedly.

The second severe loss to the medical faculty is caused by the death of Prof. Luithlen, the dermatologist, in his fifty-eighth year. He, too, had been closely associated with the work of Prof. Mayer and had investigated the pharmacology of the skin, publishing numerous papers, also, on pemphigus, scleroderma, and elephantiasis. At one time he was assistant to the famous Kaposi.

Lactation.

At the last meeting of the Gynæcological Society of Vienna Prof. Kraul read a paper in which he dealt with the physiology of lactation. This condition, he said, brings about a regular alteration of the blood picture; there is leucocytosis, eosinophilia, and lymphocytosis. The vasomotor centres react in a different way in the lactating woman to adrenalin and caffeine, and the lactating mother is less prone to glycosuria than the non-lactating. There is also increased tone in the vagus. In 75 per cent. of all lactating women the typical amenorrhœa of lactation is found. This is caused not by an absence of ovarian function, but by cystic degeneration and over-rapid maturation of the follicles; at the same time there is hypofunction of the hypophysis. The vegetative nervous system acts (so to say) as an intermediary between metabolism and ovary on the one hand and the rest of the gland of internal secretion on the other. Most investigators are not of this opinion, believing that the mammary glands produce their secretion because they are not stopped by the ovary. In abnormally protracted lactation loss of ovarian function is certainly found; but as there are wet-nurses who are regular in their monthly periods although they are producing large quantities of milk, Prof. Kraul does not accept the theory that the ovary controls the breast. It is noticeable that the appearance and condition of women often greatly improves after childbirth, which suggests that lactation has a considerable influence upon the general health and disposition.

BUCHAREST.

(FROM OUR OWN CORRESPONDENT.)

Seaside Sanatorium for Surgical Tuberculosis.

THE Ministry of Public Welfare has long been considering the establishment of a seaside sanatorium for the cure of surgical tuberculosis in children. The Government, however, has been unable to set aside the necessary funds, although convinced that such a

nstitution is needed, and the Society of Rumanian Charitable Women therefore proposes to raise the money required. With the same object a number of addresses have been given at the Bucharest Medical Society and elsewhere, at which it was pointed out that successful sanatoriums have been set up along the sea-coast in many countries and that—contrary to experience with adults—salt air and sea-bathing seem to be the best possible treatment for scrofulous conditions in children. Their usefulness in surgical tuberculosis is less certain, but, as an English surgeon said not long ago, it is scarcely justifiable to treat this condition in the hospitals of large cities. In orthopædic hospitals the necessity for fresh air and sunshine is well understood, and the children sent to country homes during the summer come back wonderfully improved.

Fees of Medical Practitioners.

The general increase in the cost of food and clothing and the rise in rent and especially in taxes has involved the raising of medical fees in Rumania, despite the appreciation of currency in the last few months. As, however, there is a Ministerial decree which establishes a minimal scale of fees in the different towns and in general throughout the country, most people pay only this minimum. When actions are brought for recovery of fees the civil court always orders the defendant to pay the fees laid down by regulation. The fees of general practitioners, however, are not determined on this basis, and most towns and local associations have announced a rise of 30 per cent. in their scale of payment, this change being seldom opposed. In towns of less than 30,000 inhabitants, taking families of moderate income with four to five members, the annual fee of the medical adviser is 1000 lei (about £5); in Bucharest the fee is from 5000 to 12,000 lei. These are paid in half-yearly instalments; extra payment sometimes has to be made for night calls and consultations, for visits to sanatoriums and hospitals, and for obstetric and surgical operations. In view of the fact that the average fee for attendance at the patient's home amounts to 100 to 150 lei (about 3*s.*) in the larger towns and 100 lei even in the smaller towns, it may be said that the present financial position of the medical profession in Rumania is satisfactory.

Diphtheria in Serbia.

In a recent report of the Chief Sanitary Board of Yugoslavia it is stated that during the decennium 1915–25 8736 cases of diphtheria were notified in the old kingdom of Serbia, with a mortality of 2117, or about 25 per cent. Of the cases notified antitoxin was given in 5234, and in these the mortality was about 21 per cent.; in the cases not treated with antitoxin, on the other hand, the mortality was no less than 46 per cent. Apart from curative treatment 14,276 persons were given prophylactic injections of antitoxin. They were all members of households invaded by diphtheria, and 54 of them were afterwards attacked by the disease, 19 of the cases proving fatal. In the whole series of people treated curatively and prophylactically, abnormal after-effects were noted in only 24 patients. These effects comprised serum rashes (8), erythema (4), roseola (2), local inflammation at the site of the injection (3) and abscess (4), painful elbow-joint (1), pain in the leg and swelling of the foot (1), and suppuration in the middle ear (1).

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENT.)

Psychiatry and the Law.

THE American Psychiatric Association held its annual meeting last month at Cincinnati, in company with four other national societies interested in mental hygiene and abnormal psychology, and the combined meetings drew several hundred physicians from all parts of the country. The most important business transacted was the outlining of a new legal code. This lays down the need for a classification of mental disorders taking into consideration "behaviour pathology not now definitely defined or classified from a psychiatric standpoint." There are also to be laid down "official standard qualifications" of expert witnesses in psychiatry and for psychologists and social workers attached to psychiatric clinics. Various proposals by the American Institute for Criminal Law and Criminology were approved, including a recommendation that the disposition and punishment of all misdemeanants and felons be based upon a study of the individual offender by qualified and impartial experts coöperating with the courts. The indeterminate sentence was favoured, and it was agreed that no parole or discharge should be granted without full psychiatric examination. The last proposal, if adopted, will almost of necessity require the appointment of resident psychiatrists in the larger penal institutions. It was recommended that courses in criminology be given both in law schools and in medical schools by persons trained in criminal law as well as in criminal psychiatry.

Infant Mortality.

The U.S. Children's Bureau has just completed an analysis of infant deaths in eight American cities, the study covering a series of 23,000 live births. Advocates of birth control will note with interest that mortality is highest when births come in quick succession and lowest among babies born at intervals of four years or more. The possibility of spurious correlation here must not be forgotten. It may be also that the somewhat higher mortality in children of mothers under 20 years of age is due to their less fortunate circumstances rather than to their youth. Babies of mothers who died within a year of confinement had a four times heavier mortality than those whose mothers survived the first year. Mortality was lowest for infants born in August and highest for those born in June. The death-rate of premature babies was more than six times as high as that of babies born at term. The mortality drops month by month for the first year of life; it was 44·8 per 1000 in the first month, 9·3 in the second, and 4·5 in the twelfth.

Prevention of Blindness.

A successful year is reported by the National Committee for the Prevention of Blindness. Preschool eye clinics have been established, and at the end of the year three demonstration centres were at work in which children from 3 to 6 years of age were being examined. The sight-saving classes in the United States have increased from two in 1913 to 265 in 1926. The subjects considered by the classes include a survey of the schools for myopic persons in Great Britain. The committee has given attention to methods of illumination in industry and the popularisation of modern devices with employees and managers. It is satisfactory to note that the admissions to schools for the blind due to ophthalmia neonatorum are only half of what they were 20 years ago.

THE MERCHANT TAYLORS AND "BART.'S."—The Merchant Taylors' Company have agreed to contribute £7000 to the reconstruction fund of St. Bartholomew's Hospital, paying £1000 per annum for the next seven years. There is a long connexion between the hospital and the company.

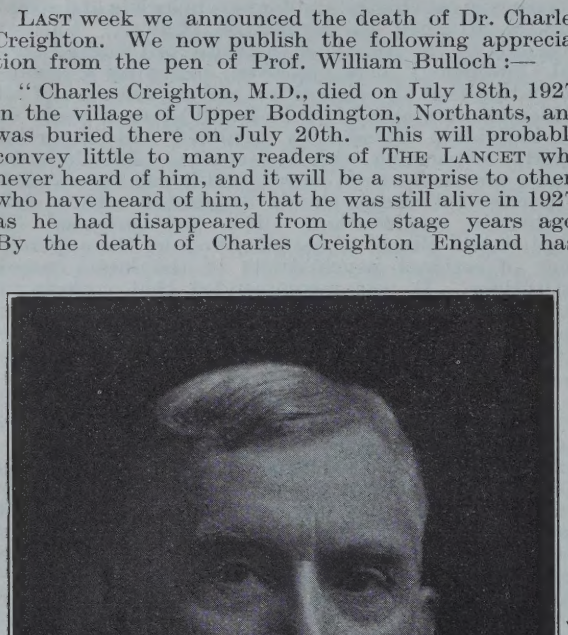
WEST HERTS HOSPITAL.—The new Marnham maternity ward at this hospital has been opened by the Marchioness of Salisbury. The erection of the ward was the chief part of the scheme of improvements and additions for which the £15,000 centenary appeal was made. Dr. Hogarth, for the Ministry of Health, which has contributed some financial assistance, said that an effort was being made to reduce maternal mortality, and that in addition to the new ward there were beds for cases of puerperal fever. The Ministry was encouraging the provision of institutional treatment for this disease in rural areas.

Obituary.

THE LATE DR. CHARLES CREIGHTON.

LAST week we announced the death of Dr. Charles Creighton. We now publish the following appreciation from the pen of Prof. William Bulloch :—

"Charles Creighton, M.D., died on July 18th, 1927, in the village of Upper Boddington, Northants, and was buried there on July 20th. This will probably convey little to many readers of THE LANCET who never heard of him, and it will be a surprise to others who have heard of him, that he was still alive in 1927, as he had disappeared from the stage years ago. By the death of Charles Creighton England has, however, lost her most learned medical scholar of the nineteenth century, although it cannot be forgotten that some of his opinions were the subject of such criticism that he ceased to be felt as a power in the medical world.



CHARLES CREIGHTON.

[*Photograph by Elliott and Fry, Ltd.*

"Creighton was born in Peterhead on Nov. 21st, 1847, the son of Alexander Creighton, a sawmiller and timber merchant of that town. After education at the Gymnasium in old Aberdeen, and having taken a high place in the strenuous examination known locally as the 'bursary competition,' he passed through the arts curriculum of Aberdeen University and graduated M.A. in 1867. He studied medicine in Aberdeen and Edinburgh and graduated M.B.Aberd. in 1871 and M.D. in 1878. He then set out on his *Wanderjahre* and spent a long time in Berlin in Virchow's Institute and in Vienna, where he attached himself particularly to Skoda and Rokitanski. Returning to this country he became medical registrar at Charing Cross Hospital and surgical registrar at St. Thomas's Hospital, and then began to occupy himself with anatomical problems and cancer research under Burdon-Sanderson at the newly opened Brown Institution in the Wandsworth-road. In 1877 he was appointed demonstrator of anatomy at Cambridge under Sir George M. Humphry, and he remained there till 1881, when he returned to London. Here he stayed for 37 years working assiduously and alone in the British Museum and other libraries. It was in the British Museum during the 'eighties, that he amassed the enormous collection of material which he employed to such good purpose in his invaluable 'History of Epidemics in Great Britain.' For a short time he had attempted to practise, first in Savile-row and then in New Cavendish-street, but he made nothing of it. He was by nature totally unfitted for this branch of medical activity. During more than 30 years he resided in chambers in Great Ormond-street, known to only a few and literally despised and rejected. At the end of the war his slender funds enabled him to purchase a small tumble-down cottage in the old-world village of Upper Boddington, and here, all by himself, he spent the last eight years of his life, like the philosopher that he was, and without enmity towards a world that had treated him harshly.

"I first met Charles Creighton at a concert given by the John Murray Minstrels about 30 years ago, and until he left London was a close friend of his. I also visited him in his sylvan retreat in Northampton. I will go further and state my belief that I was his only intimate friend for years before he died, for he was a most lonely forsaken man. To the end he was a scholar and philosopher and the most learned man I ever knew. He spoke and read nearly all the European languages and had an extraordinary knowledge not only of medicine but of the classics and the Bible. His knowledge of English literature and history was also profound. Although he frequently spoke as if he wished to be considered and remembered as a pathologist, it is by his 'History of Epidemics in Great Britain' that he earned a permanent place beside the great masters of medical history like Daremberg, Haeser, Freind, and Hirsch. In my judgment Creighton's 'History of Epidemics' is the greatest work of medical learning published in the nineteenth century by an Englishman. It covers the period from 664 A.D. to about 1890, and is written with such philosophical insight and with such literary brilliance and knowledge as to re-create for us the disastrous epidemics of centuries ago. I many cannot always agree with all his opinions and interpretations his data have never been in question. They have been examined over and over again and have been found so accurate that a citation from 'Creighton' invariably passes as an authoritative canon. I have read, re-read, studied, and analysed Creighton's wonderful book, and have never discovered an error on a question of fact, when I have examined the original sources. He had thoroughly sifted a vast mass of historical material, and relatively little—and that unimportant—has been added to his labours by subsequent workers. The volumes as they appeared were hailed as landmarks, and, although admirably got up, never sold well. In the course of a few years large numbers of 'remainders' were unloaded on the market and were sold on bookstalls in the London streets at the cost of a few shillings. It is now scarce. Creighton's monetary reward for his labour was negligible.

"In addition to his 'History' Charles Creighton conferred a lasting boon on English Medicine by his accurate translation for the New Sydenham Society of Hirsch's 'Handbuch der Historisch-geographischen Pathologie.' He accomplished the herculean task of translating this great work without any aid whatsoever. He once told me it cost him 12 hours a day for a period of three years! Had it not been for Creighton Hirsch's indispensable work would have remained *terra incognita* to the mass of English workers. In addition Creighton wrote a number of books on anatomical and pathological subjects. Among these may be named 'Contributions to the Physiology and Pathology of the Breast and its Lymphatic Glands,' 1878; 'Bovine Tuberculosis in Man,' 1881; 'Illu

rations of the Unconscious Memory of Disease,' 1886 1885]; Contributions to the Physiology and Pathology f the Breast., 1886; 'The Natural History of Cow-pox nd Vaccinal Syphilis,' 1887; 'Jenner and Vaccina- ion, a Strange Chapter in Medical History,' 1889; Microscopic Researches on the Formative Property f Glycogen' (two parts), 1896–99; 'Cancers and)ther Tumours of the Breast,' 1902; 'Contributions o the Physiological Theory of Tuberculosis,' 1908; Some Conclusions on Cancer,' 1920; 'Shakespeare's Story of His Life,' 1905. 'Shakespearean Allegories,' 912. This last work was in progress when Creighton ied.

"What can be said of these books, many of which vere published through the generosity of an early riend of Creighton? Under the influence of current eaching they seemed obscure and his standpoint ifficult to fathom. At the back of his head there was ome idea—to most of us a nebulous one—that iseases like tuberculosis or cancer were due to some yscrasia in the workings of the body. To most of is few readers his books meant nothing, and they fell ead at their birth, to Creighton's manifest chagrin. am sure he longed for the day when the eyes of the nedical world would be opened to see things as he nvisaged them. I saw the inception, progress, and nd of some of these books and argued with him on is views, and sometimes showed him things, under he microscope, which he said didn't exist; but he ould not be convinced.

"He was an extraordinary man, and 'brither Scot' hough he was, I cannot say I completely understood im. He seemed to have some mental twist which revented him seeing things as other people saw them. 'hat he implicitly believed all that he wrote I have no oubt, and he was fearless of the consequences and onest to the point of injuring himself and his prospects. Ie exhibited a complete indifference to the most hostile riticism and bore no grudge. He was contented and heerful and an admirable companion. He seemed ossessed of some cacodæmon, which was entirely nimical to worldly success, for which Creighton, owever, cared not a jot. Throughout life he was poor, lonely bachelor, leading a most frugal and hysiological life and solely concerned in digging the laim which he had pegged out by himself and or himself. He simply could not acclimatise imself to modern theories of disease. He belonged nedically to another age; he lived in a world of niasms and effluvia rather than particulate contagion n the form of bacteria. He was of the dyscrasic chool of Rokitansky in pathology. But he was in o sense of the word antiquated in his learning. His nowledge was of the most modern kind and of the idest compass. Although he was familiar with all ne methods of section-cutting and staining he inned his faith on sections cut with a razor from ssue, embedded in a 'penny dip,' and stained with ink.

"The real tragedy of Creighton's life was connected ith his views on cow-pox and vaccination. For many ears he had been the intimate friend of Robertson mith, the theologian and Arabic scholar, who was litor of the ninth edition of the 'Encyclopædia ritannica.' Robertson Smith got Creighton to write r the Encyclopædia the articles on malaria, medicine, orgagni, pathology, pellagra, and vaccination. The st-named article, published in 1888, literally sealed reighton's fate. Based on an extended study of the riginal data, he came to the conclusion that Jenner's ork was incorrect, and that cow-pox was not as enner stated 'variolæ vaccinæ.' In Creighton's ew cow-pox had nothing to do with variola and was ot a protective against variola. He even went rther and maintained that what had been described vaccinal syphilis was not venereal pox at all, but rt and parcel of the cow-pox infection in the human eing. Before the publication of the Encyclopædia rticle he had given evidence in a book published in 87 that he held this view. He was at once hailed y the anti-vaccinators as a valuable recruit to their nks and by the medical profession as a renegade to e treated with disdain and obloquy. One critic said that 'Nothing in all the history of pathology can be more grotesque, more absurd than his contention that infantile syphilis is largely due to the vaccine virus.' In a reply Creighton wrote: 'I have felt constrained to my great regret to differ from what I know well to be the solid opinion of the profession on the matter of vaccination. Anyone who takes sides with a minority or a small minority has only himself to blame. It is, of course, easier, more pleasant, and more profitable to be in the full stream of professional accord. Recusancy has its own disadvantages.' The issue between Creighton and general professional opinion on vaccination was not thrashed out there and then as it ought to have been. It was deemed more expedient to drop Creighton into oblivion, and if he was ever referred to at all it was only as 'Creighton the Anti-vaccinator.' All his other work was forgotten in the debacle, and he was a doomed man. He came to the front for a short time a decade later with some views on plague, which he had been enabled to study in India through some fund placed at his disposal. He could not be brought to believe that *Bacillus pestis* played any important part in the disease, which he regarded as merely an abstract something inherent in the soil. In his journey to the Punjab it was a peculiar pleasure for him to have stood by the Hydaspes where Alexander defeated Porus. He had no doubt that he had discovered the long-disputed site of the battle.

"In his later years, when he considered that his medical mission was done, he devoted himself to literary studies on Shakespeare and published 'Shakespeare's Story of His Life' and allegories on *Othello* and *Lear*. He also had written a large work on *Macbeth*, which he showed me in manuscript. Contrary to what might have been anticipated, he scorned the Baconian theory. His books on Shakespeare were ignored by the world, and if looked at were regarded either as incoherent or erroneous. What their significance, if any, was in Shakespearean literature I do not know. They were quite beyond my capacity. Creighton himself considered they were important.

"From all I have written it is plain that Charles Creighton could not be judged by ordinary standards. He was like a lonely rock in the great flowing tide of human progress. He was a self-contained personality, a thinker, a reader, and throughout life a diligent student. He adhered to his views with the greatest Scottish tenacity. He simply could not alter, and although he suffered grievously I never, in the long years of my acquaintance with him, heard from him a single complaint. He demanded little out of life and got less. It is pleasing to think that the anxiety of his declining years was relieved by a civil pension which he received, without any influence, from Lord Oxford and Asquith, who recognised in Creighton all the elements of a great scholar.

"In person Creighton was a tall, handsome, well-preserved man—the photograph shows him at about 60 years of age. He was throughout life fond of music and was a great walker. It is a pleasure to me to try to perpetuate the memory of a learned philospher who although by nature the very antithesis of myself, was a good friend. In the opinion of many he was harshly treated by the world for holding views that did not conform to standard. Perhaps this very world has become more tolerant than it was in Creighton's time, because even in his own subject there are epidemiologists who express with impunity to-day views as heterodox as those for which Creighton was pilloried and ostracised 40 years ago." W. B.

THE LATE DR. T. R. WIGLESWORTH.—Dr. Thomas Ridler Wiglesworth, who died at his home at Minster, Sheppey, on July 4th, was 61 years of age, and came of a Gloucestershire family. Educated at Bristol, he qualified as M.R.C.S. Eng. in 1892, and soon afterwards went abroad as medical officer to a gold mine in Nicaragua. In 1906 he settled in Sheppey as partner to Dr. Julius Cæsar, who died some months ago. For the last 20 years of his life he was medical officer to the Sheppey Rural District, besides being Admiralty surgeon for the Isle of Sheppey. Dr. Wiglesworth leaves a son.

Public Health Services.

TUBERCULOSIS SANATORIUMS.

CLASSIFICATION AND TREATMENT.

A SANATORIUM report should serve two purposes. In the first place it should provide the governing body of an institution with an account of the work done during the period under review, pointing out deficiencies and indicating the directions in which improvements should be made. In the second place it should supply information likely to be of service to other workers in the same field. Every sanatorium should be a centre of research. For while the main principles of sanatorium treatment are common to all such institutions and the benefits to be expected from a period of rest, fresh air, nourishing food, and graduated exercise are well known, we have still very much to learn concerning the results of various surgical procedures, of vaccine therapy and of drug treatment, and we have everything yet to learn of the possibility of discovering a specific antidote to tuberculosis. The difficulties of assessing the value of any particular form of treatment in a condition so sensitive to the effects of suggestion as that induced by tuberculosis are notorious. If every sanatorium (and we might add, every tuberculosis dispensary) was regarded as a research centre, if careful records were kept of every method of treatment adopted, and the results of such treatment were clearly set down, the present interminable and fruitless arguments concerning the value of certain supposed specifics would be set at rest, while much less time and money would be wasted in therapeutic procedures demonstrably ineffective.

A quotation from Sir Berkeley Moynihan is set at the beginning of the attractive report of the *Dumfries and Galloway Sanatorium* for the period included between the opening of the institution in 1924 and the end of last year. Speaking of cancer, he states that "the certainty of diagnosis is often the certainty of death. If we wait till we know, we wait till we cannot cure." The quotation is provocative. In a case of suspected malignant disease a doubtful diagnosis can be confirmed or dispelled by an exploratory operation. But the physician anxious to determine the correctness of a tentative diagnosis of pulmonary tuberculosis has no corresponding method by which he can at once set his doubts at rest. If he waits till he knows, it is by no means unlikely that the certainty of diagnosis will prove to be the certainty of death. But if he acts before he knows he may inflict the stigma that attaches to "the consumptive" on an innocent person, and condemn a patient who is in no danger of developing tuberculosis to a long period of sanatorium treatment.

The question of classification in pulmonary tuberculosis, involving as it does the question of diagnosis, is one of first importance, when a report on the results of its treatment is to be considered. No certain conclusions can be drawn as to the benefit of sanatorium treatment in general or of any special form of treatment adopted from a consideration of the so-called "T.B. minus" group. The Dumfries report includes a classification of patients suffering from pulmonary tuberculosis based on that recommended by the Ministry of Health. It is noteworthy that out of a total of 249 patients no less than 48 per cent. were classed as "T.B. minus" on admission. Thus, in nearly half of the total number of patients bacteriological proof of tuberculous infection was lacking on admission. The proportion of "T.B. minus" cases among the discharged was apparently about the same. It is to be noted further that a third of these cases were children, in whom a positive diagnosis of pulmonary tuberculosis is seldom possible. It is obviously better that statistics of children should be dealt with separately from those relating to adults. An extract from the histories of some of the patients is, however, supplied, and it is thus possible to form some estimate of the grounds upon which diagnosis was based. An extension of this system is desirable. It would be of the utmost advantage if sanatorium reports were always to include an analysis of the "T.B. minus" group indicating those cases giving a history of hæmoptysis, pleurisy, and close contact with sources of infection, as well as those in which symptoms and physical signs suggested a diagnosis of tuberculosis. Further explanation is required of the medical superintendent's comment that the group under consideration was "not wholly composed of very early cases, for tubercle bacilli are not found in a certain proportion of definitely intermediate and advanced cases." It is questionable whether a diagnosis of pulmonary tuberculosis is ever justified in the case of a patient who exhibits definite signs of intermediate or advanced disease, but whose expectoration, excretions, or secretions, have never yielded tubercle bacilli, despite careful and repeated search by a competent bacteriologist.

A further illustration of the need for more careful classification of pulmonary tuberculosis is provided by the annual report of the *Winsley Sanatorium*, a report apparently designed to meet the requirements of a lay committee alone. The "admissions" are divided into three classes, but no data are given as to the grounds on which the classification is based, nor is any reference made to the bacteriological examination of sputum except the bare statement that tubercle bacilli were found at one time or another in 136 cases out of a total of over 300. The discharged patients are also divided into three arbitrary classes. Of Class I. 77 per cent. were reported as "fit for work" on discharge; over 47 per cent. of Class II., and even 17·5 per cent. of those allocated to Class III., were declared to be in the same fortunate position. As the average length of stay of patients discharged during the year is given as 112·6 days we are driven to the conclusion either that the methods of classification are peculiar to this institution or that its treatment yields astonishingly satisfactory results. Turning to the latter we learn that "bacillary emulsion vaccine has been used with beneficial results in a limited number of suitable cases," that "the usual routine treatment was employed—namely, rest, walking exercise, and the usual grades"—whilst "tuberculin was used in suitable cases and artificial pneumothorax therapy was employed in cases which were judged suitable for it."

Those who are in charge of institutions for the tuberculous are under an obligation to their patients to provide the best treatment that our present very limited knowledge permits. There is no reason to suppose that they fail in this respect, but as indicated above, they are also under obligation to their colleagues to supply evidence of the value of every method of treatment employed. Such evidence must rest upon observed facts and deductions drawn from them. It is to be regretted when vague speculations and loose statements are given in place of scientific evidence.

The reports of the tuberculosis *After-care Associations at Walthamstow and Leyton* should be read by those who are inclined to question the value of organisations of this kind. The former in particular serves a much wider purpose than that of presenting a balance-sheet and summary of work accomplished. An introduction gives a brief account of the anti-tuberculosis campaign since the year 1912, when the Insurance Act became operative, outlines the present scheme of treatment, and explains the need for voluntary work if the scheme is to be effective. The work of a care association may make all the difference between hope and despair to a family whose head is stricken with tuberculosis. Still more important, however, is its work as an educational influence, especially to-day when there is a danger that ears deafened by the shouted exaggerations of the propagandist may fail to catch the still small voice of reason.

NFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 16TH, 1927.

Notifications.—The following cases of infectious isease were notified during the week:—Small-pox, 56 (last week 185); scarlet fever, 1553; diphtheria, 47; enteric fever, 84; pneumonia, 659; puerperal ever, 39; puerperal pyrexia, 128; cerebro-spinal ever, 4; acute poliomyelitis, 10; encephalitis thargica, 27; continued fever, 1; dysentery, 10; phthalmia neonatorum, 115. There were no cases f cholera, plague, or typhus fever notified during ne week.

Deaths.—In the aggregate of great towns, including ondon, there was no death from small-pox, 2 (1) from nteric fever, 21 (0) from measles, 3 (1) from scarlet ever, 14 (5) from whooping-cough, 20 (7) from iphtheria, 46 (9) from diarrhœa and enteritis under wo years, and 21 (0) from influenza. The figures in arentheses are those for London itself.

The Services.

ROYAL ARMY MEDICAL CORPS.

Maj. A. L. Otway retires on retd. pay on account of ill-ealth and is granted the rank of Lt.-Col.

The undermentioned Lts. (on prob.) are confirmed in heir rank: R. V. Franklin, G. Anderton, E. H. Hall, . A. Walmsley, A. Sachs, R. A. M. Humphrey, R. T. P. weedy, and T. E. Moles.

TERRITORIAL ARMY.

Maj. W. D. Watson, from R.A.M.C. (T.A.), to be Col. and .D.M.S. 54th (E. Anglian) Div., T.A., vice Col. G. A. Troup.

Maj. A. A. Hingston, having attained the age limit, is etd. and retains his rank, with permission to wear the rescribed uniform.

Maj. D. M. C. Church resigns his commn.

Capt. I. M. Pirrie to be Maj.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Lt.-Col. C. W. Eames, having attained the age limit, elinquishes his commn. and retains his rank.

Maj. F. Hauxwell, from the Active List, to be Maj.

ROYAL AIR FORCE.

Temp. Lt. H. J. Eagleson (General List, Army, Dental urgeon) is granted a temp. commn. as a Flying Officer n attachment to the R.A.F.

Squadron Leader J. R. Crolius is placed on the retired list n his own request.

AUXILIARY AIR FORCE.

No. 605 County of Warwick (Bombing) Sqd.: J. S. erome to be Flying Officer.

INDIAN MEDICAL SERVICE.

Lt. D. Kelly to be Capt.

The King has approved the relinquishment of his temp. mmn. by Temp. Lieut. Aziz Khan Mahomed Khan.

Maj.-Genl. S. F. St. D. Green to be officiating Director Medical Services in India, vice Maj.-Genl. W. H. Ogilvie, n leave. Maj. H. P. Rudolf to be Specialist in Gynæcology nd Midwifery, Lucknow District, Lucknow, vice Lt. W. cott, vacated. Capt. L. A. J. Graham to be Specialist Dermatology, Presidency and Assam District, vice aj. H. P. Hart, vacated. Capt. A. C. Chatterjee has been ppointed to act as Police Surgeon, Calcutta, vice Maj. O. De, on leave. Lt.-Col. Anthony to officiate as Surg.-enl., Bombay. Maj. S. Gordon, senior medical officer, ıob, Independent Brigade Area, has been appointed to mmand the Indian Military Hospital, Loralai, vice Capt. I. Cox, vacated. Lt.-Col. H. R. Nutt, civil surgeon, llahabad, has been appointed to Medical Charge of the ntral Jail, Allahabad, vice Lt.-Col. C. E. Palmer, on ave. Lt.-Col. W. Parr has been reposted as Civil Surgeon d Superintendent, Mental Hospital and Robertson edical School, Nagpur. Dr. Narbada Prasad Shrivastava, fficiating Civil Surgeon and Superintendent, Mental Hospital d Robertson Medical School, Nagpur, has been posted Officiating Civil Surgeon to Akola. Lt.-Col. W. S. Willmore s been appointed Inspector-General of Civil Hospitals, har and Orissa. Maj. M. A. Rahman, Principal, Agra edical School, to officiate as Civil Surgeon, Agra. Dr. ıtiaq Husain Rizvi, Lecturer on Medical Jurisprudence d Hygiene, Agra Medical School, has been appointed as edical Officer in Immediate Charge, King Edward's spital, Lucknow. Dr. B. M. Gupta, assistant public alyst, to officiate as Public Analyst to the Government, ited Provinces.

"Audi alteram partem."

VENEREAL DISEASE AND PROFESSIONAL SECRECY.

To the Editor of THE LANCET.

SIR,—There is no doubt that we should all wish to be free from a most unpleasant duty, and it may also be true that our obligation to give evidence may deter some patients from taking treatment. That side of the case is well known and has been often stated. But there is another.

First, there is at the present time no greater danger to liberty than that executive departments should be their own law makers. It has been frequently allowed of late years, but it is directly contrary to the principle that every executive officer is like every other man bound by the common law. If the Inland Revenue were involved instead of the Ministry of Health you would be up in arms at once, and the Ministry of Health is one of the worst offenders in this respect and has been bitterly complained of by medical men. I am, therefore, heartily glad on this account that its regulation has been disallowed.

Secondly, the one maxim that runs through the whole of English law and English history is that every man shall at whatever cost have justice. You argue that he is to be deprived of the evidence by which alone he can obtain it partly because it detracts from the dignity of medicine, and partly because it may damage the public health, to provide it. I have no hesitation in declaring that justice is more important than either.

I am, Sir, yours faithfully,

July 27th, 1927. W. P. HERRINGHAM.

To the Editor of THE LANCET.

SIR,—Your leading article is an opportune reminder to the profession of the persistent and insidious lay encroachment on the immemorial principle of medical professional secrecy. The past week has seen an effort on the part of a civic corporation to make it compulsory for doctors practising within its area of operation to notify to a public authority the presence of venereal disease in their patients. The Corporation of the City of Liverpool inserted in a Bill, which came for its final consideration to the House of Commons last Tuesday, the following clause:—

157. (1) In the following cases venereal disease shall be deemed to be an infectious disease to which the Infectious Disease (Notification) Act, 1889, applies (that is to say): (*a*) Any infant under two years of age suffering from any such disease; (*b*) any person (not being a child) suffering from any such disease who after being informed by any medical practitioner attending on or called in to visit him or by the medical officer that further treatment is necessary in order to effect a cure of such disease refuses or neglects to undergo such further treatment: Provided that notwithstanding anything contained in the said Act it shall not be the right or duty of any person other than a medical practitioner to give notice to the medical officer of any case of venereal disease.

(2) In this section the expression "venereal disease" has the same meaning as in the Venereal Disease Act 1917.

This clause (No. 157) forms part of a document of 136 folio pages. It attracted no general attention, and it was only the timely intervention at the last moment of a small group of Members, of whom I was one, that saved the enforcement of this monstrous rule upon the medical profession of Liverpool. The legislation which thus narrowly escaped enactment is in flagrant conflict with the regulations laid down by the Local Government Board in 1916 for the conduct of medical departments established for the prevention and treatment of venereal diseases. These orders contained these significant suggestions:—

5. "The arrangements for out-patient treatment will form the most important part of the scheme of the Council,

and these arrangements will vary to some extent according to local circumstances. But in all cases it will be important to arrange *that the clinics are not specially designated as for venereal diseases and that nothing is done to distinguish the patients who attend for treatment of these diseases.*" (The italics are in the original.)

6. . . . " The medical officers will probably find it necessary to obtain the names and addresses of patients for the purpose of subsequent communication with them and in order to arrange for continuity of treatment, but this information should not be used for any other purpose whatever. By Article II. (2) of the Regulations, all information obtained in regard to any person treated under a scheme approved in pursuance of the Regulations must be regarded as confidential, and it is essential for the success of any measures designed to deal with venereal diseases that patients should be fully assured as to the secrecy of the arrangements."

The purpose of these regulations is obviously to encourage the early treatment of venereal disease by shielding the patient from any publicity that could possibly be avoided. The forms in use at St. Mary's Hospital (which I enclose) demonstrate the elaborate precautions there taken to conceal the identity of the patient.

Your report says that Mr. Justice McCardie, in the case you comment upon, ruled that " in a court of law the doctor had no privilege similar to that held by a solicitor or other legal adviser." I believe that public opinion is ripe for the extension of that privilege to medical advisers, however strongly the legal profession may oppose such extension, and that the medical profession would be forcing an open door in demanding that the privilege of professional secrecy shall be enjoyed by them upon the same terms as by the lawyers.

I am, Sir, yours faithfully,

E. GRAHAM LITTLE.

House of Commons, July 25th, 1927.

To the Editor of THE LANCET.

SIR,—Your admirable leading article deserves, and has I am sure earned, the gratitude of the great majority of those whose work lies in the treatment of the diseases mentioned. Not infrequently a married patient has asked me whether all information that is given will be treated in absolute confidence even in the event of legal proceedings being instituted in the future. I have always assured patients that I considered that all information given in professional confidence could not under any circumstances honourably be divulged except with the patient's sanction and that I should maintain this attitude even in a court of law.

I think that the very great majority of medical and lay opinion would certainly support this view when the question involved was anything short of crime. I am not at all certain that a majority would not include all crimes, with the exception of murder, as venereal infection is not infrequently associated with sexual crime. As you rightly observe, " if protest is to be treated as a mere formality . . . . the public will soon learn to distrust the alleged secrecy," and I think those doctors who have conscientious scruples in betraying a professional secret should be willing to go to prison for conscience sake, as honourable men have so frequently been called upon to do in the past, rather than be coerced into what they consider a dishonourable act.

The law is, after all, only the wish of the people, and if a large number of people desire the alteration of a law, and a small number of people are willing to sacrifice themselves in order to obtain such alteration, it certainly will not be long before legal effect is given to the wishes of the people. In my opinion, the prevention and cure of venereal disease demands that professional secrecy should be maintained at all costs.

I am, Sir, yours faithfully,

H. WANSEY BAYLY.

Harley-street, W., July 25th, 1927.

THE MORTALITY FROM HÆMATEMESIS.

To the Editor of THE LANCET.

SIR,—I have read with great interest the communica tion from Dr. Ernest Bulmer in THE LANCET last wee concerning the mortality from hæmatemesis observe at the General Hospital, Birmingham. Like a statistical inquiries, it is likely to give rise to erroneou deductions, and as such deductions may lead t changes in the treatment of such cases, it is well t call attention to one or two points arising from h paper.

In the first place, Dr. Bulmer has given figur which concern the mortality amongst all cases i whom hæmatemesis was so severe as to lead t admission to hospital. His figures, therefore, repr sent the mortality in a highly selected group patients. They represent the mortality among patients exhibiting obvious and massive bleeding, an my first point is that they must not for a moment b taken to represent the risk of death amongst a patients who bleed from a peptic ulcer. Still mo must we avoid imagining that they give any inde of the risk of death from hæmorrhage among patients suffering from either acute or chronic ulcer tion of the stomach and duodenum.

It is to be noted that Dr. Bulmer's figures ha been quoted for a period of more than 24 yea The total deaths from hæmatemesis in that peri were 67 in all, or in other words, fewer than thr persons per annum die from this cause in the Gene Hospital, Birmingham. A minute's reflection I think, sufficient to convince one that the mortali from hæmatemesis is unimportant when contrast with the risk of death from perforation or fr operative interference and its complications.

The figures collected by me from the post-mort records of the Middlesex Hospital, and those quot by Dr. A. F. Hurst from the records of Guy's Hospit appear to show a lower mortality-rate from hæm emesis than do those recorded in Dr. Bulmer's pap It is not suggested for a moment that this differe is in any way due to fundamental differences in t treatment adopted in various hospitals, but it m well be explained in part by existing ambular facilities, as Dr. Bulmer himself says, or, again, t may to some extent be due to the number of medi beds in our hospitals reserved for emergencies, s opposed to routine medical admissions.

Whatever be the explanation, I do not think t careful examination of Dr. Bulmer's figures properly lead to the conclusion that death fr hæmatemesis is a very important risk amon patients suffering from ulceration of the stomach duodenum. I need not add that in stating t I make no suggestion that such hæmorrhages are very serious complications of peptic ulcer, and o which make the institution of careful treatm necessary in all such cases.

I am, Sir, yours faithfully,

T. IZOD BENNETT

Harley-street, W., July 25th, 1927.

DIET AND DIETISTS.

To the Editor of THE LANCET.

SIR,—In an endeavour to deal with the assert made by some of the advocates of whole wheat b bread that " cancer, appendicitis, and many o diseases are the result of the use of white bre the letter which appears over six signatures in y last issue calls for the serious attention and sideration of your readers. In that letter g stress is laid upon the biological value of vitami and its presence in white bread because yeast, w is believed to be rich in that vitamin, may have made use of in leavening our loaf. I would obse however, that your correspondents overlook fact that yeast is used in bread making not bec of any elusive or mysterious vitamin which it

ld to the bread, but because it attacks the sugar id generates carbon-dioxide, producing thereby a ght and spongy loaf. It is, of course, common nowledge that in the aeration of the loaf of bread east may be dispensed with altogether, and as a atter of fact much of the bread found on the market -day, which is equally as light and spongy as that ade with yeast, has been made by incorporating ready formed carbon-dioxide with the dough.

I would point out, moreover, that your correspondnts who have subscribed to the aforesaid letter ke no thought of what happens to their vitamin B white bread when so-called chemical improvers specially a chemical improver like persulphate of otash) are incorporated with the dough containing east. The persulphates are believed to act as idising agents, but, because of the gluten in bread, persulphate of potash is the improver used persulate of ammonia may be formed, and acting as reducing agent this persulphate is likely to destroy ny vitamin which may have been introduced into e bread by the yeast.

I am, Sir, yours faithfully,

Harley-street, W., July 23rd, 1927. JAMES OLIVER.

To the Editor of THE LANCET.

SIR,—With reference to the present controversy n the merits of wholemeal as opposed to white read, the following facts may be of interest. The opulation of the Punjab consists of roughly ,000,000 of people. The immensely larger proporon of this population is concerned, either directly indirectly, in the cultivation of the soil. Their diet nsists of wholemeal bread and dal, varieties of ulses with large quantities of cooked and uncooked getables, and many varieties of fruit. There is no uestion of the wholeness of the meal. It consists of e whole grain coarsely ground in stone querns worked hand and is subjected to very little sifting or sieving. is meal is worked up into a dough with water d patted out into a sort of flat cake between the nds and then lightly scorched upon heated iron eets or "tawas." These cakes of unleavened bread m the staple diet of these millions from whom the lk of the soldiers of the Indian Army are drawn. eaking as a surgeon who has practised and lived ongst these people for the past 25 years, I can tify to the great rarity of such diseases as pendicitis, gastric and duodenal ulcer, gall-stone ease and visceroptosis amongst them, and, finally, the infrequency of cancer in any of its forms. I sh it to be understood that I am referring to the icultural and pastoral tribes of the Punjab and t to the literate and clerical classes, many of ose members have departed in a greater or less gree from the simple habits of their forefathers.

Owing to the irresistible and continuous operation the laws of caste and custom, there can be few ople whose diet has altered less during the past 0 years or so, and in so far as the physical condition a people is an expression of their diet, the physique the average Punjabi may be regarded as the ultant of dietetic factors which have been at work on a whole race for many thousands of years hall be asked, "What are the results of these dietetic tors which have been in continuous operation for many years?"

Vell, to commence with, rickets in any shape or m is rare in the villages. The Punjabi mother kles her own infant. If from any cause the mother nable to suckle her child it usually perishes, since tle-feeding is unknown amongst this people. w many a time have I not seen amongst the women Anglo-Saxon stock the desire and the inability to se their own children. The teeth of the Punjabi magnificent; caries is rare, and it is common to men of 40 years of age and over with 32 teeth and a trace of caries in one of them. The toughness vitality of the Punjabi peasant is proverbial in North of India, and I must reluctantly confess that their physique compares very favourably with that of the inhabitants of these islands.

There is one remarkable respect in which the Indian soldier differs from his British comrade, and that is in his strikingly smaller liability to appendicitis. I took the trouble to work out the averages over a period of some 17 years for the two armies in India, and found that the incidence for British troops was just ten times greater than in the Indian Army. Here we have two bodies of men, either in the prime of life or in the flower of their youth, undergoing the same training, exposed to the same climatic influences, performing the same duties, in which we find that the incidence of appendicitis is just ten times greater in the red meat and white bread eaters than in the wholemeal bread and pulse eaters. The large amount of cellulose in this diet of wholemeal and pulse provides an efficient element of "roughage"—in the absence of which the intestine appears to be unable to perform its functions properly—and leads to a regular and frequent discharge of the waste products of digestion, and a consequent immunity from that intestinal stasis from which all civilised peoples suffer in a greater or less degrees.

To sum up: We find that the nation which subsists on a diet of pulse and wholemeal bread enjoys a striking immunity from the very diseases and disabilities from which our own people suffer so grievously, albeit they are nourished on that wholesome white bread which arouses the admiration of some of our food specialists. On the other hand, we have a C3 race with a dentition so debased and decayed that they are unable even to masticate the emasculated paste which masquerades under the title of bread in this country, mothers who are unable to suckle their own children, widespread stunting and deformity from infantile rickets, an appallingly high percentage of rejections for physical unfitness amongst those recruits who present themselves for the army and navy, and finally a cancer mortality of one death in ten as certified in our bills of mortality returned by the Registrar-General.

He who can find a cause for satisfaction in such a state of affairs must in very truth be a super Mark Tapley.

I am, Sir, yours faithfully,

July 25th, 1927. H. HALLILAY.

To the Editor of THE LANCET.

SIR,—Will you kindly allow me to mention that THE LANCET of Oct. 29th, 1921, states: "The suggestion that the loss of vitamins in the germ may be compensated by baking with yeast has not been substantiated." The Public Health Report of the United States Public Health Service for May 3rd, 1918, describes experiments made on pigeons using fermented white bread, and states: "The addition of yeast (in amounts used by bakers) in the preparation of bread from highly milled flour does not prevent the appearance of polyneuritis in birds fed on this food, but prolongs slightly the period of incubation." Recent researches described by Prof. Drummond show that the "requirements of the higher animals for vitamin B are quantitatively related to the food catabolised in the body." The amount required is, therefore, considerable. Finely ground whole-meal is an easy and cheap method of obtaining our daily need of vitamin B.

The abstraction of mineral salts from white flour is most injurious, for foods which have been deprived of these vital constituents do not support life. Whole wheat contains five times more phosphorus than fine white flour. When combined with the lime found especially in green leafy vegetables the essential phosphate of calcium results by interaction in the body. This is essential for the formation of bone and teeth and the nourishment of the nervous system. Important digestion experiments made by the Royal Society prove that bread containing 90 per cent. of the wheat grain can be generally digested, provided it is ground to a uniform fineness so that every particle will pass through a 16th-inch mesh wire sieve. Bread

and flour constitute about two-fifths of the weight of food consumed by people of limited means, and are almost the sole food of many poor children whose mothers have neither the money nor the time to prepare the varied diet which enables wealthy people to utilise white bread. Scientific experiments and practical experience show that *finely* ground whole wheat meal bread is a healthy, nourishing food, suitable for all classes of the community, and being sold cooked, ready for eating, is a great advantage for poor overworked mothers.

It is hoped that all interested in the welfare of children will study this important subject, and endeavour to secure for the country a bread which will be a real staff of life, and give poor children a better chance of obtaining healthy bodies with good bones and teeth and well-nourished brains and nerves.—I am, Sir, yours faithfully,

MAY YATES,
Founder and Hon. Secretary, The Bread and Food Reform League.

37, Essex-street, London, W.C., July 22nd, 1927.

*** We have received, among other contributions to this controversy, a letter from Dr. Henning Belfrage, reaffirming the position which he took up last week, and suggesting that in view of the different medical opinions enunciated the Medical Research Council should give the matter early attention. —ED. L.

SEPARATION OF "CONTACT" CHILDREN OF TUBERCULOUS FAMILIES FROM HOME INFECTION.

To the Editor of THE LANCET.

SIR,—The experience of the Grancher organisation in France of "boarding out" the "contact" children of school age of tuberculous families, and of Léon Bernard, Debré, and Calmette, of the separation of infants from birth to school age at centres associated with a creche at the Hôpital Laennec, Paris, is well known now in this country as of proved value in the prevention of tuberculosis.

Plymouth made a start in this direction in 1924 by establishing a hostel for "contact" children of all ages, in premises in the suburbs of the town leased from the War Office, and its good work is fairly widely recognised here. Up to the present the hostel has depended on voluntary subscriptions, as the coming flag day on July 23rd, 1927, but the committee believe that they will receive support in the future from public bodies, such as health committees, boards of guardians, and others.

Practically all tuberculosis schemes employ systematically an expensive staff of doctors and health visitors to examine the "contacts," and advise the heads of the family of the necessary measures for prophylaxis, but in the majority of cases there is not the least possible chance for such advice to be carried into effect by the family, owing to adverse social conditions, especially the general lack of accommodation in the home and the loss of wages and income attendant on disablement from the disease. In fact, the examination of "contacts," speaking from a practical aspect, is a great waste of public money, because it begins and ends with advice.

The hostel system of separation of "contact" children, as practised in Plymouth, supplies the required means to the end in view, and is complementary and not a rival to the "boarding-out" system as advocated and practised in this country at St. Leonards-on-Sea by Dr. W. Bolton Tomson, and by the London County Council and by Dr. G. Jackson, F.R.C.S., at Plymouth.

Both systems deserve the support of public health and tuberculosis care committees and the community in general.

I am, Sir, yours faithfully,

F. G. BUSHNELL,
Member Plymouth Borough Public Health and Tuberculosis Care and After Care Committees.

Plymouth, July 15th, 1927.

QUININE AND CHINOSOL SUPPOSITORIES

To the Editor of THE LANCET.

SIR,—Some of the comments by Dr. Norman Ha on the letter published in THE LANCET of July 2 on behalf of the Medical Research Committee of t C.B.C. may confuse your readers. His Americ surgeon friend, who "was convinced" that a pati "had become sterile" as a result of using "chino jelly" is beside the mark; we were not discussi a "jelly," but giving the result of over 800 ca using a *greasy* suppository.

Then Dr. Haire says: "Chinosol has been wid used for this purpose for some years . . . . but t results . . . . have been even less satisfactory th those obtained with quinine," thus implying that th is no novelty in our Committee's communicati On the contrary, members of that Committee initiat discussion on the application of chinosol to cont ceptive problems years ago, and about three ye since they instructed the manufacturer to produ varieties for their investigation. The earlier ty were not satisfactory, but were doubtless (like m things done by the C.B.C.) immediately imitat All accurate evidence is valuable and would appreciated by our Committee, and on its beh I ask Dr. Haire, whose "results with chinosol" *gre* suppositories were "unsatisfactory," what stren chinosol was used and what were the ingredients the suppository?

The perfected form we have tested on over 800 ca can hardly yet have been tested by outsiders as was announced in your columns only on July 2nd

I am, Sir, yours faithfully,

H. V. ROE,
Hon. Secretary, C.B.C., Medical Research Commit

108, Whitfield-street, London W., July 25th, 1927.

CANCER OF THE LUNG.

To the Editor of THE LANCET.

SIR,—I have read Dr. J. B. Duguid's article and y leading article on this subject with much inte (THE LANCET, July 16th, pp. 111 and 125). F the clinician's standpoint it seems desirable to re to one or two points where wrong inferences m possibly be drawn.

Everyone is agreed that the incidence of ca of the lung is high in this district. But I do not th we are agreed that this increase has occurred wi the last few years. I regard Dr. Duguid's Tab as going far to prove that the incidence has l fairly constant for the past 25 years, and that increase began about that length of time Table II. does not seem to me to negative that. must be quite 17 years ago that a well-known profe of pathology at the end of his first week's wor Manchester remarked to me, "We have had two P on cancer of the lung this week, and during all time at —— hospital I only saw a couple." remark seemed to me to show that it is true the incidence in Manchester is greater than elsewh and that it began to be greater a good many y ago—certainly before the influenza epidemic 1918–19. I quote it here as I think the infer may be drawn from your leading article that increase is very recent, and to draw such an infer might at the present juncture have the effec guiding any further investigations in a wrong direc

As a clinician I have one or two other rem to make: (1) It might be assumed that the incid is limited mainly to the working classes. This i no means the case; in Manchester we have several well-known public men from this disea recent years. (2) I have no statistics with rega tobacco, but I think that in almost every case I seen and known of the patient has been a re smoker, generally of cigarettes. To this there been the following exceptions: (*a*) Two ladies succumbed to the disease unusually rapidly.

ch case the lady lived "hard by" a railway station, here trains frequently stopped, and where smoke om the engines must have at almost all times ervaded both house and garden. (*b*) A group of ute adolescent cases, all males, in which I regard e condition as being usually mediastinal Hodgkin's sease.

I was surprised to find when demonstrating two these cases to some members of the American ter-State Post-Graduate Assembly two years ago at they were looked upon quite as curiosities, but have since found that numbers of medical men in is country also have never met with the disease, at least have never recognised it.

I am, Sir, yours faithfully,

Manchester, July 18th, 1927. FRANK E. TYLECOTE.

POOR-LAW HOSPITALS.

To the Editor of THE LANCET.

SIR,—Dr. F. J. O'Donnell's article in THE LANCET July 16th (p. 116) is full of constructive criticism. o touch upon one point only, there can be no uestion that the mass of patients in Poor-law ospitals must provide unrivalled opportunities for inical research. From the surgical standpoint, the hospital is properly equipped, these opportnities are almost inexhaustible. Unfortunately, e professional degradation, which is inseparable om being associated with Poor-law, often deters ose who are best fitted from participating in the ork. At the present time, I think, British surgery considerably hampered by an absurd dilemma. n the one hand, there is the assistant surgeon the large teaching hospital, trained to the hilt, en, and in every way fitted to undertake surgical search, but paralysed because he is "bedless," or most so (according to locality) during what are, tentially, the most productive years of his short e. On the other hand, there are thousands of rgical beds under Poor-law administration, staffed, many instances, by those who have had comratively little surgical training, and have no desire aptitude to further their science and art. It can ly be to the interests of the public and the profession large to see that this absurdity is rectified.

I am, Sir, yours faithfully,

Birmingham, July 18th, 1927. HAMILTON BAILEY.

"TENNIS LEG."

To the Editor of THE LANCET.

SIR,—Your annotation (July 9th, p. 78) and Dr. P. James's letter (July 16th, p. 143) on this subject ll, I hope, help to emphasise the value of early ysical treatment for all muscle injuries when open eration can be avoided—this in spite of the someat scant praise in your annotation which reads: "There can be little doubt, we think, of the benefits be obtained by massage and heat and early or mediate gentle movement in the slighter cases of s not uncommon lesion."

It is always refreshing to see tribute paid to the neer work of Wharton Hood, and it is sad to think, Dr. James tells us, that his book is out of print. annot help feeling, however, that physical treatnt has advanced since Wharton Hood's day, and t perhaps Dr. James might be able to hasten overy still more if he were to avoid the preliminary t for 48 hours. At the end of this time, he advises to "get the patient to walk, or rather hobble, ut."

Among many similar cases, I shall always call to mory one Saturday morning at hospital, where was working hard in my department in order get off in time to go down early to the inter-'varsity rts. About 11.30 the Cambridge first string in high jump hobbled into the department, unable put his heel to the ground; while at practice he ruptured a few fibres of the gastrocnemius at their insertion into the soleus tendon. He arrived well within an hour of the injury, and for the next hour or so I devoted myself to the forlorn hope of being able to turn him out in the afternoon. Not only was he able to jump, but he won the event, and thereby, incidentally, the sports for Cambridge. One of my most treasured letters is that which he wrote me the same evening, in which he says: "You were the means of pulling the fat out of the fire for Cambridge, so we all owe you a debt." Before, and since, I have always regarded the high jump as a dull event, but I still remember the interest it had for me that day, and my anxiety lest the strapping should prove too loose to support adequately, or so firm as to impede freedom.

Would it not be well if the value of physical treatment were more widely recognised for this type of injury, and if opportunity were given to those who carry it out to start their treatment at the earliest possible moment?

I am, Sir, yours faithfully,

Park-crescent, W., July 18th, 1927. JAMES MENNELL.

TETANUS FOLLOWING INTRAMUSCULAR INJECTION OF QUININE.

To the Editor of THE LANCET.

SIR,—I read with great interest Dr. J. Macqueen's note on four cases of tetanus following intramuscular injection of quinine in THE LANCET of June 18th. I had a similar case about three years ago in which the incubation period was considerably longer than in Dr. Macqueen's cases—namely, two months.

An adult, 40 years old, a member of H.H. the Amir Abdulla's staff, suffered from tertian malaria while on pilgrimage in Mecca in 1924. The administration of quinine by the mouth up to 2 g. daily was ineffective. He was then given 1 g. of quinine bihydrochloride into his left deltoid. The rigors stopped and he returned to Amman in perfect health, not even complaining of irritation at the site of injection. Two months later I was called to see him and found that he had already developed trismus and the injection site was sore; no other wound could be detected. He died 24 hours afterwards in spite of intraspinal injection of antitetanic serum.

In this case the skin had been painted with 10 per cent. tincture of iodine; the syringe and needle were boiled for 20 minutes; the quinine ampoule was prepared by a well-known French company; the remaining 11 ampoules of the box were injected into companions of the deceased who are all in perfect health to-day. Nevertheless, it must be admitted that tetanus spores introduced with the needle gave rise after an incubation period of two months to a sudden fatal attack of tetanus.

For the avoidance of such a calamity I suggest that quinine should not be given by intramuscular injection, or if it must be so given, that a prophylactic dose of antitetanic serum should be given at the same time.

I am, Sir, yours faithfully,

DJAMIL F. TUTUNJI,
Private Physician to H.H. the Amir Abdulla.

Amman, Transjordania, Palestine, June 29th, 1927.

THE LATE DR. R. A. BAYLISS.—After a long illness Dr. Richard Arthur Bayliss died on July 6th at Weston Park. He was the son of Richard Bayliss, of Spondon, Derbyshire, and was educated at Loughborough School and St. Thomas's Hospital, London, qualifying as M.R.C.S. Eng. in 1890. He spent two years as house surgeon at Ryde Infirmary, and went to Bath in 1897 as resident medical officer to the Royal Mineral Water Hospital. Later he took up private practice in the town, but in 1912 he had to stop this work owing to poor health. For many years he was connected with the Bath Eastern Dispensary. When he retired he went to live in the western district, and became a member of the parish council. Dr. Bayliss was a man of many interests, including horticulture, photography, and cricket. He was married in 1900 and leaves a widow with a son and a daughter.

BRITISH AND AMERICAN NEUROLOGISTS.

MEETING IN LONDON.

A JOINT meeting of the American Neurological Association and the Section of Neurology of the Royal Society of Medicine has been held in London this week, the chair being occupied successively by Sir JAMES PURVES-STEWART and Dr. CHARLES L. DANA (New York).

At the Tuesday meetings the first paper was one by Dr. BERNARD SACHS (New York) and Dr. SIDNEY SCHWAB (St. Louis) on Symptomatology of a Group of Frontal Lobe Lesions, with a Study of Personality Alterations. The so-called classical symptoms of these lesions were, they said, so often absent that it had been difficult for the surgeon to see the cases at the early stage at which they were operable. They presented a study of 25 cases; in 10 the lesion was in the right frontal lobe, and in 15 it was in the left; and in each case the diagnosis was either confirmed at operation or post mortem. Six of the 25 patients died; five of them died following or soon after operation, whilst the sixth came into hospital suffering from pneumonia and died within 48 hours, not having been operated on. In ten the tumour was a glioma, in seven an endothelioma, in two an abscess, in two a gumma, in one an arachnoid cyst, in one a chronic inflammatory mass surrounded a foreign body, whilst in one there was a large basal-celled carcinoma involving almost the whole left frontal lobe. The symptoms far the most frequently present were emotional changes, and changes in the optic disc. Unilateral tremor was present in only five of the cases, in three of which it was on the side opposite to the lesion. They had not found it a very reliable symptom. They laid much stress diagnostically on a weakness of the lower facial muscles on the side opposite to the lesion and also on the mental change, which was of a gradually progressive character, with a striking weakening of memory for recent events.

Dr. GORDON HOLMES spoke of the many cases of gunshot wounds he had had the opportunity of seeing in which the area damaged was the frontal lobe. In some the mental symptoms were very prominent, though in others there were none. Optic atrophy or disturbance of the sense of smell was to be expected only in the case of basal lesions, when there was direct pressure on the olfactory bulb or tract or upon the optic nerve. He agreed about the significance of facial weakness and mental change.

Dr. JAMES COLLIER agreed with Dr. Gordon Holmes. He then read a paper entitled Retraction and Ptosis of the Eyelids in Ophthalmoplegia. In rare instances, he said, retracted lids might be the only sign of a lesion in the mesencephalon, the lesion in these cases being further forward than was the lesion productive of ptosis and a small pupil. He had seen cases of Parkinsonism which showed ptosis, and he had under care now a case of Graves's disease with marked ptosis.

Dr. W. PENFIELD (New York) read a paper on Cicatricial Contraction in the Brain. This was a study of the actual minute mechanism involved in the healing of cerebral scars, and the movements of cerebral tissue towards the injured area. It was illustrated by microphotographs. His conclusion was that a contracting scar of cerebral tissue must destroy a larger proportion of brain tissue than would result from removal of an equal amount of such tissue by operation.

Dr. GORDON HOLMES and Mr. PERCY SARGENT jointly contributed a paper on Endothelioma Compressing the Optic Chiasma. It dealt with ten cases of this form of tumour arising above the diaphragma sellæ and pressing on the optic nerves. These tumours were accessible to surgery, and where they had not attained a very large size could be completely removed; hence the importance of early diagnosis. The tumour was a typical endothelioma in all ten cases. In three of them it was attached to the anterior clinoid process; in two it was large enou to compress the base of the brain. In one case the were epileptiform seizures, and in one the sense smell was defective. Points in the differentiation these from stalk tumours were given in a table.

Sir EDWARD SHARPEY-SCHAFER (Edinburgh) ga an account of his observations following experiment severance of cutaneous nerves in his own perso He had been able to show that interference wi function produced by squeezing was recovered fro very much sooner than interference caused cutting with a knife.

Mr. NORMAN DOTT (Edinburgh) related a case Unilateral Hydrocephalus in an Infant in which successfully operated. The circumference of the he diminished by 3 cm. in three weeks.

Prof. EDWIN BRAMWELL (Edinburgh) described tw specimens. The first was an intracranial aneurys which arose from the posterior communicating arter The third nerve was flattened out over the surfa of the aneurysm, and immediately surrounding t aneurysm there was much pigmentation of the bra The patient was a woman aged 31, and the histo was of seven weeks' duration. Symptoms were first headache in the frontal region, followed in fortnight by intense pain in the region of the rig eye, with giddiness and vomiting. Diplopia followe with practically complete palsy of the third ner A fortnight after admission to hospital she sudden developed acute symptoms and died, the later pha suggesting rupture of an aneurysm.

The other specimen was to illustrate corti deafness, in a woman aged 62, whose brain I Bramwell exhibited. There must in this case ha been an embolus involving the arterial supply to t temporal lobe on either side. Post mortem, there w seen to be extensive softening involving the upper t temporal convolutions on the left side, and on t right side a softening which, on the surface, involv the supramarginal gyrus and parts of the tempo convolutions. Only five or six cases had be reported, said Dr. Bramwell, in which comple deafness resulted from a bilateral temporal lesion

Dr. J. A. KILLIAN read a paper written by hims and Dr. M. OSNATO (New York) on the Chemi Composition of the Blood and Spinal Fluid n Epilepsy. Many attempts had been made, they sa to ascribe the ætiology of epileptic seizures to a me bolic basis, or to trace those seizures to a change the composition of body fluids, but little biochemi evidence had been produced to support this c tention. Their investigation had shown t epilepsy did not essentially entail impairment of re function, nor of protein metabolism—sufficiently any rate to modify the protein catabolites in blood. At the time of an epileptic seizure there a decrease in the blood cholesterol, and within 24 ho of the seizure the blood contained 15 per cent. cholesterol than did normal blood. There was a in these cases, an increase of lactic acid in the blo

Dr. HENRY COHEN (Liverpool) read a paper sett out the results of his chemical studies on the for tion of the cerebro-spinal fluid. His object was ascertain whether the central nervous system m any contribution to the fluid. He and his colleag were able to show that every known chemical cha in the cerebro-spinal fluid could be grouped un one of four headings: (1) substances normally greater quantity in the blood than in cerebro-sp fluid were always increased in meningitis; (2) s stances always present in greater quantity in cere spinal fluid than in blood decreased in meningi (3) substances which were normally present in blood but normally absent from the spinal fl passed into the spinal fluid in meningitis; (4) s stances injected into the blood and under nor conditions not passing into the cerebro-spinal fluid meningitis passed into that fluid. The explana was that the choroid plexus was damaged meningitis, so that its permeability was increas hence the composition of the cerebro-spinal fl tended to approximate to that of the blood plasm

Dr. J. FAVILL (Chicago) discussed the relation of e ocular muscles to the semicircular canals in tationally induced nystagmus. He had attempted systematise 26 different combinations of endo- mph current or movement and assign to each a ecial response in the form of nystagmus; and he id he was able to predict from his findings the kind nystagmus which would occur. He suggested that is knowledge might be applied to the early cognition of labyrinthitis.

Dr. A. C. BUCKLEY (Philadelphia) read a con- ibution setting out his observations concerning imitive reflexes, as revealed in abnormal mental ates.

Dr. JOHN ECKEL (Buffalo) read a paper by himself id Dr. N. WINKELMAN (Philadelphia) entitled oductive Endarteritis of the Small Cortical Vessels Severe Toxæmias. This was a study of the minute scular changes following the ingestion of tainted eat and other foods, and was illustrated by many des.—Dr. R. M. STEWART said he was interested to e that though one of the patients described had acute phritis and the other had not, the picture presented both was very similar. He thought the miliary ci and the softening which were found might have en due to a mild syphilitic infection of the cortex. Dr. GORDON HOLMES referred to a number of men had seen during the war, who were in a dug-out hen a slowly burning poison shell came into the ench. Ten men were taken from it alive, most of em in an unconscious state. A few days later he as asked to see one of them as he had developed a nfused mental state and various ocular palsies. week later he had seen another of the men, who id suddenly become violently maniacal, and subse- iently died within a few days. He had an oppor- nity of examining some of the brains, and changes ere apparent in them very similar to those Dr. ckel described. In the cases which Dr. Holmes w there was vascular proliferation, considerable crease of reaction in the middle layers of the rtex and in the third and fourth layers. He under- od from chemists that the slow combustion of the ell in question produced large quantities of carbon noxide.—Dr. ECKEL replied that both the blood d spinal fluid gave a negative Wassermann.

Dr. EMANUEL MILLER discussed Mental Dissocia- n, its Relations to Catatonia, and the Mechanism Narcolepsy, based on the case of a woman, aged 26, o complained of periodical attacks of disorientation, ring which she was only vaguely aware of her roundings. There were also periods during which sation was disturbed down the left side of the dy, lasting from a few minutes to several hours. out one in every ten cases of hysteria noticed that a emotion frequently brought on sleep or a state of ntal dissociation. He frequently noticed the ationship between sleep and hypnosis. In hypnosis subject passed through a phase of catalepsy with idity and relaxation.

Dr. ADOLF MAYER (Baltimore) referred to the earches of Dr. Percival Bell on this subject, and ecially on the correlation of lesions in the sub- lamus in connexion with disorders of sleep. The inary person's life consisted of the waking life l the sleeping life, and only the former had been quately studied. How the nervous system was olved in the sleeping life would be one of the most portant spheres of experimentation for the next years.

NATIONAL PLAYING FIELDS.—Lord Woolavington sent a donation of £5000 to the Duke of York's national ing fields appeal. This brings the present total to over 5,000.

ISOLATION HOSPITAL EXTENSION.—Mr. Godfrey ker-Lampson, Under Secretary of State for Foreign irs, has opened the extension of the Hornsey, Wood n, and Finchley Isolation Hospital at Muswell Hill. cost of the extension is estimated at £28,000.

Medical News.

UNIVERSITY OF OXFORD.—At a Congregation held on July 23rd the following degrees were conferred :—

B.M.—O. Hooper, R. C. Probyn-Williams, J. W. Pugh, H. W. Allen, C. Charleson, J. L. Glover, P. F. Cluver, and Irene M. Titcomb.

The Theodore Williams Scholarship in Pathology has been awarded to Joyce Wright, Somerville College, and J. G. Reid, University College.

UNIVERSITY OF CAMBRIDGE.—Henry Barcroft, B.A., of King's College, has been elected to the Michael Foster Studentship awarded annually for the encouragement of research in physiology.

UNIVERSITY OF LONDON.—A meeting of the Senate was held on July 20th, Sir William Beveridge, the Vice-Chancellor, in the chair.

Miss D. L. Mackinnon, D.Sc. Aberd., was appointed as from August 1st, 1927, to the University Chair of Zoology tenable at King's College.

Dr. Mackinnon is at present Reader in Physiology at King's College and has published numerous articles and translations. She is a Fellow of the Royal Society of Tropical Medicine.

Prof. E. H. Kettle, M.D., M.R.C.P. Lond., was appointed as from Oct. 1st, 1927, to the University Chair of Pathology tenable at St. Bartholomew's Hospital Medical College.

Since 1924, Dr. Kettle has been Professor of Pathology and Bacteriology in the Welsh National School of Medicine, Cardiff. He studied at St. Mary's Hospital Medical School and graduated in 1907 taking the M.D. degree in Pathology in 1910. In 1907 he was appointed Assistant Pathologist, and in 1920 Pathologist, to St. Mary's Hospital. Later he became Director of the Department of General and Special Pathology in the newly formed Institute of Pathology and Medical Research. He is Vice-President of the Pathological Section of the Royal Society of Medicine and has examined for the Universities of London and Cambridge.

Mr. Bronislaw Malinowski, D.Sc. Lond., was appointed as from August 1st, 1927, to the University Chair of Anthropology tenable at the London School of Economics.

Mr. W. H. Linnell, Ph.D. Durh., was appointed as from the same date to the University Readership in Pharmaceutical Chemistry tenable at the School of Pharmacy.

Since October, 1926, Dr. Linnell has been Lecturer in Pharmaceutical Chemistry and Director of the Chemical Research Laboratories at this School.

The London School of Hygiene and Tropical Medicine (Departments of Bacteriology and Immunology, and of Epidemiology and Vital Statistics) was admitted as a School of the University, and the date of the appointment of Prof. W. W. C. Topley and Dr. Major Greenwood to the respective University Chairs in these subjects, tenable at this School, was changed from August 1st, 1928, to Oct. 1st, 1927.

The degree of D.Sc. was conferred on Mr. A. S. Parkes, of University College, for a thesis on the Occurrence of the Œstral Cycle after X Ray Sterilisation.

At recent examinations, the following candidates were approved :—

M.D.

In Medicine.—W. L. Ackerman, London Hospital; Doris M. Baker, St. Mary's Hospital; John Bevan-Jones, University College Hospital; T. S. Blacklidge, Guy's Hospital; R. T. Brain, London Hospital; Grace D. Chambers. London (R.F.H.) School of Medicine for Women and St. Mary's Hospital; A. C. M. Elman, University College Hospital; J. A. James, University of Bristol and London Hospital; A. T. Jones, University College Hospital; Georges Klionsky, St. Bartholomew's Hospital; Marjorie Low, London (R.F.H.) School of Medicine for Women; H. V. Morlock, St. Bartholomew's Hospital; Jean L. Smith, University College, Cardiff, and Charing Cross Hospital; Hilda N. Stoessiger, London (R.F.H.) School of Medicine for Women; H. C. C. Taylor, Guy's Hospital; Joseph Whitby, Middlesex Hospital, and Caroline I. Wright, Charing Cross Hospital.

In Pathology.—Joan M. Ross, St. Mary's Hospital; Doris M. Stone, London (R.F.H.) School of Medicine for Women.

In Psychological Medicine.—G. C. Berg, St. Thomas's Hospital; May K. Ruddy, Charing Cross Hospital.

In Midwifery and Diseases of Women.—F. C. Alton, St. Thomas's Hospital; Harold Burt-White (*University Medal*), St. Bartholomew's Hospital; Dorothy N. L. Leverkus, London (R.F.H.) School of Medicine for Women.

In State Medicine.—E. K. Macdonald, St. Thomas's Hospital and Royal Institute of Public Health.

M.S.

In Surgery.—D. H. Patey, Middlesex Hospital.

ROYAL SOCIETY OF MEDICINE.—The Society's house will be closed during August for the annual cleaning and repairs. The library will be open on week-days (excluding Monday, August 1st) from 11 A.M. to 6 P.M., except on Saturdays, when it will close at 1 P.M.

SOCIETY OF APOTHECARIES OF LONDON.—At recent examinations the following candidates passed in the undermentioned subjects:—

Surgery.—L. Ashkenza, Middlesex Hosp.; E. Clayton-Jones, Guy's Hosp. J. Miller, St. Bart.'s Hosp.; J. D. Ritchie, St. George's Hosp.; and E. A. Stroud, Birmingham.

Medicine.—A. F. Briglmen, Edinburgh; E. Clayton-Jones, Guy's Hosp.; W. H. Collins, London Hosp.; and B. Elliott, Durham.

Forensic Medicine.—S. A. Carr, Birmingham; E. Clayton-Jones, Guy's Hosp.; S. Goldman, London Hosp.; and S. B. S. Smith, St. Bart.'s Hosp.

Midwifery.—E. Clayton-Jones, Guy's Hosp.; P. F. Fanaken, St. Mary's Hosp.; and J. D. Ritchie, St. George's Hosp.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: E. A. Stroud and E. Clayton-Jones.

UNIVERSITY OF EDINBURGH.—The Earl of Balfour, as Chancellor of the University, presided on July 28th, when the honorary degree of Doctor of Laws was conferred on the following members of the medical profession:—Prof. Vittorio Ascoli, Prof. Harvey Cushing, Prof. C. L. Dana, Lord Dawson of Penn, Prof. Archibald Donald, Dr. C. E. Douglas, Prof. Knud Faber, Sir William Hale-White, Prof. Jan van der Hoeve, Mr. R. G. Hogarth, Dr. William Hunter, Prof. Otto Meyerhof, Prof. T. H. Milroy, Sir Berkeley Moynihan, Prof. Otto Naegeli (in absentia), Sir John Parsons, Sir Humphry Rolleston, Prof. G. F. Still, Prof. W. S. Thayer, Mr. Wilfred Trotter, Dr. T. M. Tuffier, and Sir Almroth Wright.

The University Court has received the resignation of Prof. G. Lovell Gulland from the chair of medicine.

SCOTTISH BOARD OF HEALTH.—The Board has appointed Dr. Alexander James Muirhead and Dr. Hugh Miller to be district medical officers (medical referees). Both Dr. Muirhead and Dr. Miller have been for some years engaged in private and panel practice.

THE HOMŒOPATHIC CONGRESS.—The ninth quinquennial Congress of Homœopathic Practitioners was held recently in London. Medical men and women from North and South America, India, and from many European countries were present, and medical, surgical, and special subjects were discussed in 12 different sections, some 70 papers being read in English, French, and German. The treatment of cancer was discussed by many speakers, and it was agreed that recovery from the disease may occur without surgical intervention. The view was generally adopted that some constitutional condition underlies and precedes the local lesion and that medicinal treatment, to have prospect of success, must stimulate the body to supply the necessary antidotal or protective substances.

THE LATE DR. H. C. NIXON.—The death is announced of Dr. Horace Clulow Nixon, physician to the Royal Mineral Water Hospital, Bath, and late medical superintendent of the Ministry of Pensions Hospital, Harrogate. Born at Leek in Staffordshire in 1877, he was the son of Benjamin Barlow Nixon, and was educated at Sedbergh School, St. Bartholomew's Hospital, and the Universities of Dublin and Edinburgh. Graduating M.B. Edin. in 1900, he became assistant demonstrator of pathology in the University, and later house surgeon at Huddersfield Royal Infirmary. Thence he went to the North Staffordshire Infirmary, where he worked until 1905. In 1904 he proceeded to the M.D. degree with commendation. During the late war he served as surgeon in the navy, and he afterwards was medical officer in charge of out-patients at Edmonton Military Hospital. He went to Bath from Harrogate about three years ago. Dr. Nixon was an accomplished pianist and composed songs and pianoforte music under the name of Horace Clulow. He leaves a widow and a youn daughter.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—A special course in Diseases of Infants has been arranged by Dr. Eric Pritchard to take place at the Infants Hospital from August 8th to 21st, and will occupy each afternoon from 2 P.M. On both Saturdays and on one Sunday special visits to institutions have been arranged. From August 29th to Sept. 10th an all-day course will be held at the Queen Mary's Hospital, Stratford, including demonstrations of medical, surgical, orthopædic, and ophthalmic cases, besides operations and lectures. The subjects of special courses in September will be: medicine, surgery, and the specialties at the Westminster Hospital; diseases of children at the Queen's Hospital; psychological medicine at the Bethlem Royal Hospital; ophthalmology at the Royal Westminster Ophthalmic Hospital, and orthopædics at the Royal National Orthopædic Hospital. The Fellowship also arranges a general course of instruction at the associated hospitals; particulars will be sent on request. Copies of all syllabuses and of the *Post-Graduate Medical Journal* (annual subscription 6*s.*, post free) may be had from the Secretary at 1, Wimpole-street, London, W. 1.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

POOR-LAW RELIEF IN WEST HAM.

ON Thursday, July 14th, Mr. BARNES moved:—

"That an humble Address be presented to His Majes praying that the Order, dated the 17th day of June, 1927, ma by the Minister of Health under the Board of Guardians (Defaul Act, 1926, and entitled the West Ham Union Default Ord (Continuation) Order, 1927, be annulled."

He said that when the Guardians (Default) Act w introduced last year the Minister of Health had proposa before the country for the reorganisation of the Poor-la and the Minister described the Default Bill as a tempora measure. Now political circumstances appeared to making the reorganisation of the Poor-law, as far as a ne Act of Parliament was concerned, rather remote. Therefo he thought that those who represented the West Ha district were entitled before another six months' period administration and power were given to the appointe guardians to have a full statement of the Minister's polic and his views in regard to the Union of West Ham. wished to submit to the Minister that instead of continui the board of appointed guardians in this district for further six months it would be better to have a full a impartial inquiry into the whole of the circumstances.

The Effect on Mothers.

Mr. GROVES seconded the motion. He said that t reduction in relief granted in West Ham had meant maln trition in mothers, and the fever hospital was full. T list of women waiting to enter the sanatorium was ve much greater at this moment than before. Dr. and M Watkins, and the matron, Miss Davis, of the Plaist Maternity Home, stated that since the reduction of rel in West Ham the constitutional and physical appearar of the mothers and children attending the Plaistow matern clinic was obviously a process of deterioration. With rega to infantile mortality up to 1919, West Ham was amon the highest of the industrial towns in the country. Betwe 1919 and 1926—in the era of this assumed extravaga Poor-law relief—it was an evident fact that the infan mortality of West Ham was amongst the lowest of t industrial towns, and since 1926 the rate was stead moving in the wrong direction. The guardians had presen Report No. 2, in which they indicated that they had redu the amount of relief per person from 8*s.* 5½*d.* to 5*s.* 6½*d.* week per head. For the week ending March 19th, 1927, 1 school-children who previously were fed in their own hom their parents being in receipt of Poor-law relief, had atten the dining centres connected with the schools because th parents had had their relief drastically reduced by the n board of guardians. Connected with the county boro of West Ham there was a department associated with th clinic and maternity centres where they supplied dried m a commodity which was accepted by the Ministry of Hea and the medical profession generally as being a very nutriti form of food. To the very poor people they gave away packets of the dried milk. When the applicants were destitute they sold the milk at half price, and in many c where people could afford to pay they sold it at cost pr Some 8402 persons who used to pay the full amount could not do so, and came to them to obtain the dried m at half price. There had been 12,150 extra packets of milk supplied, which cost £607 10*s.*, and 388 additio packets of milk at half price, at a cost of £9 14*s.* A result of the reduction in the amount of Poor-law r people had been forced to demand this social service f the county borough of West Ham, and they had incur in addition to the £10,988 18*s.* on extra meals supplied additional expenditure of £617 4*s.* in supplying dried m He did not think that the Minister of Health would dis the general statements of medical officers of health it seemed almost impossible to arrest the progress of tu culosis while unemployment and destitution prevaile this country. The policy of the present guardians in W Ham was a policy of hardship and a policy of persecu of the very poor.

A Comparison in Vital Statistics.

Miss SUSAN LAWRENCE said she was going to mal comparison in vital statistics between West and East Ha

Year.	London.	West Ham.	East Ham.	Year.	London.	West Ham.	E Ha
1919	13·6	13·3	9·9	1923	11·4	10·6	
1920	12·8	12·9	10·3	1924	12·2	11·5	8
1921	12·5	12·1	10·2	1925	11·9	10·8	12
1922	13·5	13·3	11	1926	11·4	10·6	4

ondon, and Kensington. The general death-rates for ondon, West Ham, and East Ham for a period of eight ears were shown in the table given above.

All through these eight years West Ham, with its desperate overty, was only once above the London general death-ate per 1000, and East Ham had always been below it. he would take a much more sensitive figure—the rate of fantile mortality over the eight years. There was a idden and beneficent change in the general infantile ortality-rate after the year 1918, and London dropped om 108 to 85. Each year it had gone down with some cillations, until it had reached 64. During those years est Ham was only three times worse than London. East am was only once worse than the London level, and that as last year. The figures were:—

Year.	London.	West Ham.	East Ham.	Year.	London.	West Ham.	East Ham.
1919	85	86	69	1923	61	60	51
1920	76	74	60	1924	69	78	54
1921	81	75	63	1925	68	66	53
1922	75	81	62	1926	64	56	68

It would be seen that 1926 was the first year in which ast Ham was above the London figure, and that was due an extraordinary first quarter, when the infantile mortality uched the unprecedented figure of 97. Considering the hness of London it was a miraculous thing that West am should be so often a little below the London average. ow she would take Kensington, and ask the House to note w the West Ham mortality figures under their guardians d their town council compared with those of Kensington:—

Year.	West Ham.	Kensington.	Year.	West Ham.	Kensington.
1919	86	102	1923	60	70
1920	74	83	1924	78	75
1921	75	107	1925	66	79
1922	81	84	1926	56	61

According to the figures of the medical officer of health Kensington the death-rate in North Kensington in 1922 s 91; in 1923 in West Ham it was 60, and in North ensington 86; in 1924 the figure for West Ham was 78, d in North Kensington 87. In 1925 in West Ham the ure was 66, and in North Kensington 88. In 1926 the ure for West Ham was 56, and for North Kensington 79. est Ham was a district which bordered on the river, and ne of it had been reclaimed from the river, and even now was flooded at certain times, whilst North Kensington s situated in a healthy district. The only thing in ich they could say that West Ham was better off than rth Kensington was that it used to have guardians who l look after the poor, and the only difference was in the le of relief which had been adopted. She had shown t the rate of infantile mortality in West Ham over a g period had been very unsatisfactory. The figures the last two quarters of 1926 did not show any very at change, the West Ham figures following the London ures at a rather increasing distance. Taking the quarter led in September, 1925, in London the infantile mortality s 55, and in the quarter ended September, 1926, it was In West Ham it dropped with London from 59 in ptember, 1925, to 55 in September, 1926. In the last arter of 1925 the figure in London was 88, and in the last arter of 1926 it was 74. In West Ham it was 72 in the quarter of 1925, and 69 in the last quarter of 1926. e Registrar-General's figures for the spring quarter wed a rise of five points in the infantile mortality over whole of London, as compared with the corresponding arter ending on March 31st, 1926. The figure was 71 March, 1926, and 76 in April, 1927. The West Ham figures wever, according to the Registrar-General, showed a jump 33 points, the infantile mortality in West Ham in the arter ending on March 31st, 1926, being 56, while in the arter ending on March 31st, 1927, it was 89. That was errific jump. In East Ham there was a phenomenal t quarter in 1926, with a mortality of 97. A year before was only 58 in the corresponding quarter, and this year was 98. She knew how difficult it was to deal with ntile mortality figures over a short period, and that one ht to be extremely cautious in drawing any conclusion. re did not seem to be any general disturbing cause, such he weather, or the London figures would have shown it. could she find any evidence of infantile epidemics icient to account for it. It seemed to her highly probable t the restriction of relief had made the mothers in much se case to face confinement and birth than they were ear ago. That view was somewhat confirmed by the ers of the infirmary. What she was asking was that the Minister should grant an inquiry. She had given the gross infantile mortality figures. The real index, however, was not the deaths under 1 year, but the deaths under 1 month and under 1 week. If they could have those, and add to them the figures for stillbirths and miscarriages for the period, they would get what was the most sensitive index of all—namely, the condition of the mothers at the time when they came to bring forth children. She urged that they should have a really scientific investigation, showing the effect of liberal relief and of restricted relief.

The Reply of the Minister of Health.

Mr. CHAMBERLAIN, replying to the debate, said it was quite true that West Ham in the past had a very good record in the matter of vital statistics, and he was disposed to take the infantile mortality-rate as a very fair measure of the general condition, not merely of the infant population, but of the population as a whole. It was quite true that for some considerable time the infantile mortality-rate in the West Ham Union had been well below 105 of the big towns in the whole of Great Britain. In January of this year the rate in the great towns was 100, and in West Ham it was 91. In February the figure was 114 in the great towns and only 94 in West Ham. In March the figure for the great towns was 87, and 84 in West Ham. Only in one month—April—were the figures in West Ham actually higher than in the great towns. He thought they were 74 for the great towns and 82 for West Ham. Hon. Members had evidently done hard labour to try to find some cases which would throw discredit on the West Ham guardians. Yet they had been extraordinarily unsuccessful. The charges which had been made against the guardians had not been substantiated. The old guardians were done away with because they were no longer able to perform their functions for financial reasons. When they got a saving at the rate of nearly £1,000,000 a year without inflicting any serious hardship or injury on any deserving person, it seemed to him that they had shown to demonstration and beyond the possibility of contradiction that the condition of the Union was due not to the circumstances, bad as they might be, in which it found itself through exceptional unemployment and the want of any large section of well-to-do people, but to methods which were quite unnecessary and which had gradually led to general demoralisation. Under the new guardians the examination of individual cases was done with a care which was entirely new to West Ham, and the relief which was given was adapted to the needs of the individual instead of being given indiscriminately. Improved accommodation had been provided for the hospital staff, workshops had been provided for the training of mental defectives, and consideration was now being given to the treatment and the nursing of the sick poor in their own homes. It was quite clear that if the present guardians were removed from office and they returned to the system of election they would return again to the chaos and demoralisation which existed before. Such a reactionary step would be a disaster for West Ham.

The motion for the Address was negatived by 170 votes to 68.

HOUSE OF LORDS.

MONDAY, JULY 18TH.

MEDICAL AND DENTISTS ACTS AMENDMENT BILL.

The Earl of PLYMOUTH (Captain Gentleman-at-Arms), in moving the second reading of the Medical and Dentists Acts Amendment Bill, said that as a result of the establishment of the Irish Free State, and of the legislation consequent thereon, medical students of universities in the Irish Free State graduating after December 6th, 1922, ceased to be entitled to registration as a right by the General Medical Council (that was, they ceased to be entitled to practise in this country), and the General Medical Council ceased to have any authority over the medical profession and any control over medical education in the Irish Free State. That state of affairs was regarded by the authorities both in the Irish Free State and in this country as undesirable; and at the request of the Irish Free State Government negotiations were begun in 1923 with a view to the restoration, as far as was consistent with the altered status of the Irish Free State, of the position existing prior to the establishment of the Irish Free State. Meanwhile, the General Medical Council agreed to continue to enter medical graduates from the Irish Free State on the register pending the passage of such legislation as it might eventually be decided to introduce. But all such registrations since December 6th, 1922, had no legal validity, and one of the objects of the present Bill was to validate them. The negotiations referred to had for various reasons been prolonged; but they had at length resulted in the agreement which appeared as Part I. of the schedule to this Bill. Sir Donald MacAlister, the President of the General Medical Council, had taken a prominent part in all the negotiations, and the agreement

had the concurrence and support of the Council. It would also be observed that the agreement had been signed by Sir Richard Dawson Bates, Minister of Home Affairs, on behalf of Northern Ireland. The agreement provided for the creation of a Medical Council in the Irish Free State which would establish an Irish Free State Register (to which all medical practitioners registered in this country and Northern Ireland would be admissible as of right) and would have complete control of that register and of the profession in the Irish Free State. On the other hand, the General Medical Council would continue to admit to the United Kingdom Register all persons who, prior to the establishment of the Irish Free State, would have been admissible thereto in respect of qualifications obtained in the Irish Free State, and for the purpose of keeping the United Kingdom Register and controlling the examinations giving the right of admission thereto the Council would retain in the Irish Free State, all the powers formerly possessed by them. Certain alterations in the Irish representation on the Council consequential on the establishment of the Irish Free State were made by Article 2 of the agreement.

The Dental Agreement.

On the completion of the medical negotiations, said the Earl of Plymouth, discussions were opened regarding the dental profession, in which an almost precisely similar state of affairs had arisen. Sir Francis Acland, chairman of the Dental Board of the United Kingdom, took part in the discussions, and no difficulty was found in reaching an agreement very similar to the medical agreement. That agreement would be found in Part II. of the schedule. Both agreements required legislation both in the Irish Free State Parliament and in the British Parliament. An Act confirming the medical agreement had already been passed in the Irish Free State and had received Royal Assent, and it was very desirable that the agreement should be brought into force as soon as possible by the passage of this Bill. The Irish Free State Bill to confirm the dental agreement had not yet been passed into law, but it was anticipated that it would be reintroduced and passed into law at an early date. The Irish Free State legislation, in addition to confirming the agreements, had to provide for the establishment of the new medical and dental authorities in the Irish Free State; it was therefore much longer and more complicated than the present Bill, and for that reason had been divided into two Bills. There was no necessity for a similar division of the legislation on this side.

The Bill was read a second time.

POLLUTION OF RIVERS.

Lord MILDMAY OF FLETE called attention to the position in relation to the pollution of rivers. He said that on Feb. 15th last the Lord President of the Council on behalf of the Prime Minister received a very representative deputation which approached him with a view to impressing upon the Government the necessity of dealing with the growing menace of river pollution. Their case in effect urged what had been proposed over and over again by many Royal Commissions and committees for 50 years past. They asked that a central authority should be established to control inland waters and that local river boards should be created in support of that central authority. They also urged the necessity for scientific research designed to solve the innumerable problems attendant on the abatement of pollution. The deputation was organised by a joint committee of the British Waterworks Association and the Salmon and Trout Association, but the two associations were supported by many other bodies, including the National Association of Fishery Boards, the Association of Medical Officers of Health, the Federation of British Industries and the Federation of British Anglers, the Council for the Preservation of Rural England, and the Pure Rivers Society.

Two Methods of Attacking the Problem.

The Earl of BALFOUR, Lord President of the Council, said the Government were entirely in agreement with Lord Mildmay that the pollution of rivers was a great evil and an evil which was increasing. Population was growing, and with population inevitably came the difficulties of sewage. The habits of the people were altering, and they were altering in a manner which, very admirable in itself, inflicted a greater and greater strain on the water-supplies of the country. The pollution from manufacturing sources was augmented at the same time. There were only two possible means, so far as he was aware, by which this embarrassing problem could be attacked. One was increased efficiency of administration, and the other was increased knowledge. The Government proposed to do all they could to further the first method of attack. In many cases it was quite impossible to give a decision in favour of the purity of rivers and against the continuance of manufactures. It was on the manufactures that the population lived. The only possible way of dealing with the situation was to find some scientific method by which they would be able to get over the difficulty which was presented not by th weakness of the law, but by the difficulty of dealing wit the laws of nature. He entirely agreed, however, tha more coöperation was required, and that it was well wort considering whether the present system of river boarc administration might not be extended with advantag and that possibly fresh legislation, or whether the amendmer of existing legislation, might be carried through. The bod which was to deal with that should not be a department body, but an inter-departmental body. It could not be a executive body, as some of his noble friend's supporte would desire. That would mean a new Government Depar ment with a Minister responsible to Parliament. But th Government did think that there should be an advisor committee representing the Ministry of Health and th fishery boards, and they had already decided on the chairma of that Committee, Sir Horace Monro. The Committee wou set to work to deal in an advisory capacity with ne legislation, with setting up new river boards, with inducir responsible local bodies to coöperate with each other ar with carrying out all those admirable objects on which h noble friend had dilated. But do not let their Lordshi suppose that nothing was being done, or had been don to diminish the curse of polluted rivers. The worst of the sources of pollution was sewage, and he was informe that in the financial year ended March 31st last loans we sanctioned by the Minister of Health of no less th £2,500,000, not for dealing with sewage as a whole, but f diminishing the sources of sewage. Authority was giv for loans amounting to £5,000,000 to deal with sewag and one-half of that sum had been devoted to the purpo of preventing sewage from further polluting the rivers this country. He hoped and believed that their knowled of how to deal with the greatest of all the evils—name sewage—was increasing. There was a Royal Commissi which before the war made a very large number of repor and made special mention of a method of dealing with sewa called by the somewhat unattractive name of activat sludge, which they were of opinion was of great promi It had been largely used in the Birmingham area and el where. There still remained much to be done in bring that process, and perhaps others, to the point of succe but on the Committee dealing with the scientific and resea side of this problem, which was being set up by the Gove ment, the gentleman who was at the head of the admira work done in the Birmingham district would find a pla

The Scientific Research Committee.

He could give the names of those who would form Scientific Research Committee. They were: Sir Rot Robertson, K.B.E., F.R.S., Prof. V. H. Blackman, F.R Prof. F. G. Donnan, C.B.E., F.R.S., Sir Alexander Houst K.B.E., C.V.O., Mr. H. C. Whitehead, M.I.C.E., and Dr Bourne, F.R.S. To these gentlemen would be added assessors Mr. H. G. Maurice, C.B., Ministry of Agricult and Fisheries; Mr. W. L. Calderwood, F.R.S.E., Fish Board for Scotland; Mr. D. Ronald, M.I.C.E., F.R.S. Scottish Board of Health; and Mr. R. J. Simpson, O.B. Ministry of Health. The Director was Dr. H. T. Calv M.B.E., who was, he supposed, the highest authority this kind of investigation that they possessed. T Water Pollution Research Board was actually at w Research was also going on in Germany and Ame and also in Holland and other countries. The new Bo would see that all the information which was of value distributed to the authorities who were responsible for purity of our streams.

HOUSE OF COMMONS.

WEDNESDAY, JULY 20TH.

Tuberculosis among Slate Quarrymen.

Sir ROBERT THOMAS asked the Home Secretary whe his attention had been drawn to the far higher percen of tuberculosis among slate quarrymen working in sl as compared with those employed in the open air, o to the injurious effect of dust in confined spaces; whether he would approach quarry owners with a vie devising practical means of improving conditions.- BURTON CHADWICK (Parliamentary Secretary to the B of Trade) replied: The report of a recent inquiry ca out under the Welsh Board of Health among slate qu men and slate workers in the Gwyrfai Rural District, s that slate workers in sheds there are exposed to inju dust, and that mortality from tuberculosis is higher a such workers than among quarriers. My right hon. f is considering, with his Health Advisory Committee

ggestions in the report for further investigation, and eanwhile the question of improving conditions has been ken up with the slate quarry owners by H.M. inspectors.

Birth-rate in London Boroughs.

Sir WILLIAM DAVISON asked the Minister of Health the rth-rate per 1000 in each of the London boroughs for the ears 1901, 1911, 1925, and 1926 respectively.—Sir KINGSLEY OOD (Parliamentary Secretary to the Ministry of Health) plied: The following figures give the birth-rate per 00 population in metropolitan boroughs for 1926:—

Borough.	1926.	Borough.	1926.
ty of London	8·0	Kensington	15·1
ner and Middle Temple	6·9	Lambeth	17·2
ttersea	17·3	Lewisham	15·4

One-Apartment Houses in Scotland.

Mr. BUCHANAN asked the Secretary of State for Scotland total number of one-apartment houses built in Scotland l the total number of two-apartment houses built since 9.—Sir J. GILMOUR replied: As at June 30th last no -apartment houses and 7222 two-apartment houses e built in Scotland since 1919 under State-assisted sing schemes. No reliable information is available as to ses of one and two apartments built without State assist-e during that period, but such information as I possess icates that the number is very small.

Appointments.

ACKSTOCK, W. P., M.B., Ch. B. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Cottingham District of the County of Northampton.

RRAY, J. DOUGLAS R., F.R.C.S. Eng., Resident Medical Officer, Bolingbroke Hospital Incorporated, Wandsworth Common.

SSELL, V. I., M.D., B.S. Lond., Obstetrician to the Elizabeth Garrett Anderson Hospital.

ISHAW, E. M., M.B., B.S. Lond., M.R.C.S., L.R.C.P., Lond., Assistant Pathological Chemist to St. Mary's Hospital.

stminster Hospital: HODGES, R. C., M.B., B.Ch. Oxf., L.R.C.P., M.R.C.S. Lond., House Physician: EVANS, E. C., M.R.C.S., L.R.C.P. Lond., STANTON, R., M.R.C.S., L.R.C.P. Lond., House Surgeons.

Vacancies.

Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

Notes, Comments, and Abstracts.

BASUTOLAND: A YEAR'S PUBLIC HEALTH WORK.

Mr. R. B. Smith, Government Secretary, has presented his report on the affairs of Basutoland for the year 1926. The area of the territory, which is bounded on the west by the Orange Free State, on the north by the Orange Free State and Natal, on the east by Natal and East Griqualand, and on the south by the Cape Province, is given as 11,716 square miles. The altitude varies from 5000 ft. to 11,000 ft. above sea-level, and the climate is, on the whole, healthy. In 1818 the first Paramount Chief, Moshesh, gathered together the remnants of the various tribes which had been scattered about South Africa during the wars waged by Moselekatse and thus founded what to-day has become the Basuto nation, consisting of upwards of 540,000 souls. The territory has since 1884 been governed by a Resident Commissioner under the direction of the High Commissioner for South Africa. There were no faction fights of a serious nature during the year under review, but considerable friction continues to exist in the Leribe District, due in a measure to Chief Jonathan's great age and inability to attend to disputes amongst his people. The territory again suffered from severe drought which occurred during the latter portion of the year. During 1926 2287 patients were treated in the hospitals, showing an increase of 66 over the numbers of the previous year. The deaths numbered 123 and the operations performed totalled 2250. In the dispensaries 61,802 patients received treatment, being an increase of 2273 over the figures of 1925. There is little noteworthy to report as regards the health of the territory; it has been very good on the whole. There were no serious outbreaks of epidemic disease. Influenza was more prevalent than in 1925 and was responsible for 985 cases, but with no deaths. There were two sporadic outbreaks, 32 cases occurring with five deaths, and five cases of cerebro-spinal fever were reported with one death. Fevers of the enteric group were few in number; only 70 were reported, and the disease was of a mild type. The majority of the patients who come to the hospitals do so for surgical aid. For medical treatment they prefer dispensary treatment, after which they return to their homes. The bulk of the dispensary patients seek treatment for gastro-intestinal, venereal, respiratory, genito-urinary, and skin diseases. The free treatment of syphilis continues, and more patients are coming every year to avail themselves of this privilege. Sanitation to any extent is only possible in the Government Reserves. Maseru is the only proclaimed sanitary area, but it is hoped to bring in Leribe during next year. Plague being endemic in the neighbouring territories, three rodent destruction gangs have been constantly employed in the Maseru, Leribe, and Mafeteng districts. Considerable progress has been made in the destruction of veldt rodents, but in the townships the position is not so satisfactory on account of most buildings not being rat-proof. Every endeavour is being made to cope with the pest.

There was an increase of 33 in the population of the Leper Asylum, which, on Dec. 31st, 1926, stood at 494. There were 42 deaths during the year; seven males and one female deserted, and four males and four females were discharged.

EXERCISES FOR THE INFANT.

ALAS for the twentieth century baby! The physio-therapeutist does not spare him even at the tender age of 5 months. It appears that in Germany and in Austria there have for some time past been enthusiasts who think that the natural instincts of infants cannot be trusted to develop their muscles adequately. It has long been thought desirable by some to teach children and young persons how to breathe, and now nature can apparently no longer be trusted to show babies how to kick and crawl and bawl. Dr. Wilkes is in the proud position of having written the first book in English on this branch of the subject,[1] and no doubt he will have pleased many mothers by giving them an increased sense of importance and by indulging their laudable desires to be of use. We do not suppose that such exercises as are here described and depicted will do a healthy child any harm as long as they are carried out with discretion and restraint, but we think that any such infant would achieve the same ends on his own initiative by measures which he would find far more congenial. The illustrations and descriptions are clear and the folder, showing 12 exercises, intended to be pinned up on the nursery wall, will no doubt be a useful guide. Nevertheless, we feel that for healthy babies in their own houses such treatment is unnecessary however much some artificial aid may be desirable fo infants confined in cribs in hospital. Yet since confine infants are presumably sick, much care and supervision i necessary even there, if harmful results are not to follow.

[1] Baby's Daily Exercises: A Manual of Exercises for Infants from Five Months to One Year of Age. By Edward Theodore Wilkes, B.S., M.D., Assistant Pediatrician, Out-patient Department, New York Nursery and Child's Hospital. New York: D. Appleton and Company. 1927. Pp. 25+x. 4s. 6d.

A NEW CHLOROFORM INHALER.

THE Chiron chloroform inhaler, which we illustrate below is designed to make it impossible for liquid chloroform t

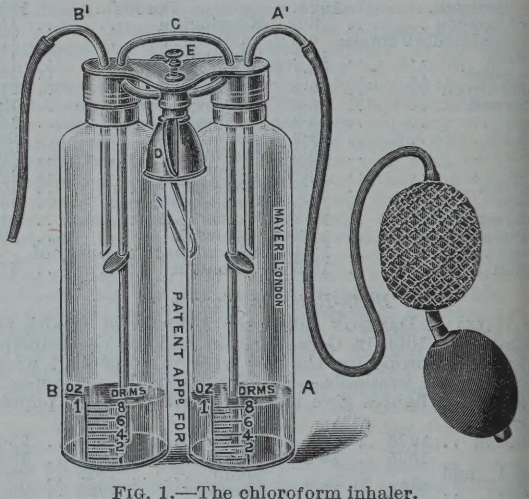

FIG. 1.—The chloroform inhaler.

be pumped to the patient, and it achieves its obje absolutely. The two means by which the accident emitting liquid chloroform has arisen are: (1) by instrumen being faultily put together, the exit tube being attached to the fitting meant for the pump, and vice versa; (2) by too much chloroform being put into the instrument. These two sources of danger cannot arise when the Chiron inhaler is used. An ingenious arrangement renders over-filling impossible, and the double bottle makes it a matter of indifference to which side the pump is attached. The apparatus is a little cumbrous to be hung from a buttonhole or used from the pocket, but a safe stand could easily be made to hold the bottles on the anæsthetist's table. We have found that the instrument can be implicitly trusted to prevent the accide against which it is designed.

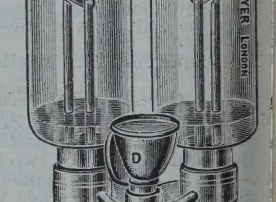

FIG. 2.—The apparatus charge in an inverted position.

The apparatus may be obtained from Messrs. Meyer a Phelps, 59-61, New Cavendish-street, W. 1.

THE HOSPITAL ALMONER'S SERVICE TO THE BLIND.

NOWHERE is the work of the hospital almoner more use than in connexion with blind and partially blind patien From the report of the work of the social service departme at Moorfields Eye Hospital we learn that the Samarit Fund is used only for urgent or exceptional cases, and th the main function of the almoner is to establish perso relations with those patients who are in difficulties, givi information, where needed, about blind societies, myo schools, convalescent homes, and so forth. To those patie who are members of societies granting "ophthalmic benefit the working of the scheme is explained and the patients a referred back to those approved societies which have agre to grant an ophthalmic surgeon's fee. In some instan the advice given is more difficult. A case is cited where young man was in the depths of despair on finding that was suffering from an incurable hereditary disease which m inevitably lead to blindness. Partly owing to the sym thetic coöperation of the almoner he seems to have discover that life is still worth living. Nor is the benefit always to t patient alone. In this case the almoner was able to coll details of the family history which were of considera interest to the surgeon.

Oliver-Sharpey Lectures

ON THE

COÖRDINATION OF THE RESPIRATION AND CIRCULATION TH VARIATIONS IN BODILY ACTIVITY.

elivered before the Royal College of Physicians of London

By C. G. DOUGLAS, C.M.G., *M.C.*, D.M. Oxf., F.R.S.,
FELLOW OF ST. JOHN'S COLLEGE, OXFORD.

LECTURE II.*

Delivered May 5th, 1927.

n my preceding lecture I discussed the various ors which ensure that the breathing shall keep with the requirements of the body as the meta- sm varies. The respiratory exchange of the ues cannot be adequately provided for merely by appropriate adjustment of the breathing, for igh the breathing may be responsible for efficient ous exchange in the lungs the transport of gases ween the lungs and tissues is a function of the ulation. If a person is at rest absorbing only e 240 c.cm. of oxygen per minute, it is clear that, n allowance is made for the maintenance of the y different organs, but a fraction of this oxygen rption can be attributed to the metabolism of cles which are thrown into activity when we move it. Yet the bulk of the 3 to 4 litres of oxygen h may actually be absorbed per minute by a on doing hard work must be utilised in these cles, and it would therefore seem that an oxygen- ly 30 times the resting value or even more have to be provided to meet the demands of muscles in such cases. Even if the blood can up its full charge of oxygen in the lungs the unt which can be carried in each litre of blood rely 200 c.cm., and we know that not nearly the e of this can be abstracted as the blood passes ugh the tissues. The demands made by the cles during hard work must therefore entail a great increase in both the local and the general lation.

ne problem of the general regulation of the circula- is a very much more difficult one to attack than regulation of the breathing. The system to be with is far more complex, and though a great of most valuable information has resulted from ative experiments on animals it must be acknow- d that methods of investigating functional latory changes in nearly intact animals and in , which can alone give us the complete answer we require, are still in their infancy.

discussing the coördination of the breathing with ges in the activity of the body I pointed out events in the organs whose activity varies must ne end set the pace of the respiratory centre. same line of argument ought to be applicable to egulation of the circulation. If a muscle passes rest into activity it is in the first instance the ratory demands of that muscle that have to be fied by the circulation, and somehow or other, it seems to me, the changes in that muscle initiate a series of events which will finally t in such an adjustment of the whole circulatory m that the necessary increased blood-supply is ned without detriment to the rest of the body.

Relation of Blood Flow Through the Muscles to Their Metabolism.

examining this question I intend to restrict lf to changes resulting from muscular activity, I am going to start with the proposition that the l flow through the muscles must be practically proportional to their metabolism, no matter whether they are at rest or whether they are at work so long as the work is not too severe. Apart from experimental observations in justification of this view, which I need not discuss as they have been fully dealt with by Haldane,[1] I put it forward on general grounds. It is obvious that too small a blood flow can only mean local asphyxia, and though we might for a moment think that a blood-supply in excess of the actual demands of the moment would do no harm though it might be extravagant, we can hardly maintain this when we recall the exactness with which the hydrogen-ion concentration is regulated in the body, since excessive blood flow will mean undue abstraction of CO_2 and a disturbance of local hydrogen-ion concentration. We have an analogous case in the breathing when deliberate over-ventilation of the lungs leads to a great reduction in the hydrogen-ion concentration in the arterial blood and definite signs of abnormality.

The Local Regulation of the Circulation.

Our ideas on the local regulation of the circulation have been profoundly modified in recent years by the classical work of Dale and Richards,[2] and of Krogh and his colleagues,[3] on capillary tone. The observations by Krogh on the limited number of capillaries which are patent in a resting muscle, and the astounding increase in visible capillaries through which blood is swiftly flowing as tonic contraction give place to wide dilatation on the onset of muscular work, afford an objective demonstration of the great increase of local blood-supply which, as I have already pointed out, must be secured during muscular activity. Why should the capillaries open up in this way? We know now that they are certainly not merely forced open by a rise of blood pressure in the arteries which supply them; their tonic contraction must first be inhibited, and if the blood flow is to be proportional to the requirements the degree of dilatation of the capillaries must be correlated with the change in the metabolism.

A very plausible hypothesis has been developed in recent years by Dale, Richards, and Burn[4] to account for these changes in capillary calibre on the basis of their investigation of the capillary-dilator effect caused by histamine. In their view some substance of a histamine-like nature, possibly histamine itself, may be a normal metabolic product and antagonise the constrictor effect on the capillaries which is known to be exerted by adrenalin and perhaps by pituitrin, for Krogh has shown that the normal tone of at least some of the capillaries in the body can only be maintained so long as the latter substance is present in the blood. This hypothesis is an attractive one, and affords a perfectly logical explanation of the functional alterations of capillary calibre, for it suggests that the continuous secretion of the suprarenal and pituitary glands tends to keep the capillaries constricted, and that this tendency may be overbalanced by the local production of a definite dilator substance whose amount will vary with the metabolism, a balance being struck with the capillaries dilated to a degree depending on the activity at the time. More recent researches in Dale's laboratory [5] on the presence of histamine and choline in extracts of the organs strengthen this position.

Relation of Capillary Tone in Muscles to CO_2 and O_2 Pressure.

And yet, attractive though the theory is, I am not convinced that we have got to the bottom of the story. Haldane and I, in an investigation of the regulation of the output of blood by the heart, to which I shall refer presently, thought that we had enough evidence to justify the view that the local circulation in the muscles must be dependent on both the CO_2 pressure (probably more correctly the hydrogen-ion concentration) and oxygen pressure existing at the time in the tissue, the rate of blood flow being in fact so regulated that the oxygen pressure and hydrogen-ion concentration will only

* Lecture I. appeared in THE LANCET last week.

vary to a trifling degree with increase of the metabolism unless the muscular activity is excessive. We held that capillary tone must be influenced as the metabolism varies by slight changes occurring simultaneously in the local hydrogen-ion concentration and oxygen pressure, a dilatation being provoked if the hydrogen-ion concentration begins to increase while the oxygen pressure begins to fall; it also appeared to us that the effect of moderate increase of hydrogen-ion concentration could be counteracted by a rise in the oxygen pressure and vice versa.† A muscle in maintaining steady activity for long periods must be absolutely dependent from moment to moment on the blood stream which passes through it for the requisite supply of oxygen and the efficient removal of CO_2, and this in itself might well arouse the suspicion that local circulation is in some way dependent on local gas concentrations. This view is, however, not necessarily incompatible with Dale's hypothesis, for it is conceivable that the extent to which some dilator substance can be formed in tissue metabolism may be itself dependent on the precise hydrogen-ion concentration and oxygen pressure in the tissue; the two latter factors will then be the prime cause of capillary regulation, the dilator substance the intermediary, through which they become effective. Finality has not yet been reached in our views, but I am convinced that we have substantial grounds for asserting that the calibre of the capillaries is directly influenced by chemical or physicochemical changes which result from alterations of the metabolism of the tissue in which they are situated.

Metabolism in Relation to Changes in Calibre of Arterioles.

Changes in the calibre of the capillaries would in themselves, however, be insufficient to satisfy the requirements imposed by variations of tissue activity unless accompanied by appropriate changes in arterial calibre. How precisely this is brought about is still a matter for debate. Krogh's work certainly inclines one to believe that there may be backward propagation of dilatation from the capillaries to the immediately adjacent arterioles via nerve channels, a local axon reflex being concerned rather than a true reflex. What adds to the uncertainty in the case of the arterioles is the fact that, as Krogh and Dale's observations show, the smallest arterioles may show a response to chemical stimuli resembling that of the capillaries rather than the larger arteries; it would appear, indeed, that the functional transition from arterioles to capillaries is gradual rather than sudden. It is also far from clear whether a similar backward propagation through nerve channels can explain, at least in part, the dilatation of the larger arterial branches which supply the terminal arterioles; it is, perhaps, more likely that inhibition of normal constrictor impulses to the larger vessels with resulting dilatation is part of the response in a reflex of the Lovén type to which I shall refer presently.

If arterioles as well as capillaries dilate locally in response to an increase in the metabolism of the part that they supply, the result must be a greater blood flow through the tissue. Blood will be transferred more rapidly from the arterial to the venous side of the active muscle, though this may for the moment mean some fall in arterial pressure unless this is compensated by other means, and the varying pressure exerted by the muscular contractions on the veins will assist to forward this increased flow of blood towards the heart.

Compensatory Constriction of Blood-vessels.

There is, however, a further general vascular reaction of great importance which must be taken into account. If the arterioles and capillaries dilate in, say, the great mass of muscles in the legs, t can only be adequately filled with blood if at same time there is compensatory constriction blood-vessels in the inactive parts of the body, the total volume of blood in the circulatory sys will not vary. That such a compensatory cons tion does occur is undoubted, and the visceral are blood-vessels in the abdomen offers the most fav able field for this compensation. Krogh [6] has discu in detail the possible influence of vasoconstric in this area, and has shown that diminution of cal of the arteries supplying the intestinal tract liver will be followed by the expulsion of part of reserve of blood held in the portal system ves into the vena cava, a result which will, of course much enhanced if the portal vessels themse undergo active contraction, and for this there is s evidence. Such an expulsion of blood into the v cava coupled with the increased blood flow fo up from the active muscle will result in a g acceleration of the venous return to the heart, this will be further favoured by the increased resp tory movements as hyperpnœa begins. No do other systems of blood-vessels besides those in portal area take part in the compensatory cons tion, perhaps even those in the skin in the e stages of muscular work, though, as we know experience, circulatory conditions in the skin subservient at a later stage, at least, to the requ ments of temperature regulation. Barcroft [7] recently drawn attention to the function of the sp as a reservoir from which blood may be withdr during muscular work, while Pembrey and colleagues,[8] in their observations on the behav of the kidney, appear to establish the fact that when rapid diuresis has been provoked a reduc in the activity of the organ associated with v constriction ensues during the performance of muscular work—under the stress the less impor demand has to give way before the more importan

Factors Involved in Vasoconstriction.

A widespread vasoconstriction must presum be spread through the vasoconstrictor nerves, in initiating these impulses two factors would ap to come into play. In the first place, we know the old experiments of Lovén that stimulation o afferent sensory nerve causes general reflex v constriction accompanied by vasodilatation in part of the body supplied by that nerve, and suggests that with the onset of muscular wo similar reflex excitation of the vasoconstr centre may perhaps be evoked by afferent pro ceptive impulses from the muscles themselves. Pos compensatory constriction in the important p area may be but a particular instance of a genera reflex of the Lovén type. In the second place, inc of hydrogen-ion concentration or fall in oxy pressure in the blood reaching the brain, the fo of which at least must occur during muscular w directly stimulates vasoconstriction in certain of the body. The second factor may well not into action so promptly as the first, but it s help to support the reflex effect.

DETERMINATION OF THE OUTPUT OF THE HEART.

The heart cannot put out more blood tha receives, nor can it fail to keep pace with the v return without the risks associated with back pre and venous stagnation; in short, the output o heart must be governed by the venous return. rate at which venous blood is returning to the is greatly accelerated with the onset of mus work, how will the heart deal with the task th set before it? Two methods are open to it pulse-rate may increase, a greater volume of may be expelled at each beat of the heart. Tha former of these two possible methods does act come into play is a matter of common experienc it was not until 1915 that Bainbridge [10] was a prove that the increased distension of the auricle, and possibly of the adjacent region o

† This view has quite recently received support from observations by Tinel (Comptes Rendus de la Soc. de Biol., 1927, xcvi., 665) on the diminution of calibre of the cerebral arteries when oxygen is inhaled or the breathing wilfully exaggerated as opposed to the dilatation resulting from rebreathing air, facts which he regards as indicative of self-regulation of the cerebral circulation.

at veins, resulting from rise of venous pressure and reased venous return to the heart caused reflex minution of the normal inhibitory action of the gus and to some degree an accentuation of celerator impulses to the heart by way of the npathetic nerves, a result which has since been nfirmed by Sassa and Miyazaki,[11] and by Anrep d Segall.[12] The observations by Patterson and rling[13] on the isolated heart-lung preparation have initely shown that in the absence of the normal ve-supply the heart can cope with an increased ous return by greater diastolic filling and an rease in the amount of blood expelled at each t, but these experiments do not tell us to what ree the heart does actually behave in this way in intact animal.

We can readily observe in man the increase of se-rate associated with exercise, but it does not ow that this will necessarily be accompanied by increased amplitude of beat, for what will actually pen will presumably depend on the extent to ich the Bainbridge reflex is developed in relation the increased venous return, since acceleration of heart beat without alteration of amplitude of t may suffice for the requirements. Clearly the ual state of affairs cannot be foretold; it must be ified by observation during life in the intact anism, and it is this point, the precise way in which heart deals with the increased venous return ulting from exercise, that has excited a good deal attention in recent years.

Krogh and Lindhard's observations by their nitrous de method[14] showed that the output of blood minute from the heart was comparatively small ilst the subject was at rest, values of 3 to 5 litres ng given in their original series of experiments, ugh slightly higher figures have been recorded some of Lindhard's subsequent work.[15] During scular work they found a remarkable increase of output of blood from the heart; thus in one of ogh and Lindhard's experiments the output rose m 3 litres per minute during rest to 17·6 litres en work was done involving an oxygen consumption 1570 c.cm. per minute, and in another experiment Lindhard's an output of no less than 35 litres per ute was recorded when the oxygen consumption s 3200 c.cm. per minute. So enormous a variation the output of the heart could only be met by a at increase both in pulse-rate and in amplitude of t, and this conclusion brought Krogh into opposi- n with Yandell Henderson,[16] who had been led a study of plethysmographic records of the heart animals to maintain that provided the venous ply is ample variation of the output of the heart lependent only on alterations in the pulse-rate.

Miss Christiansen, Haldane, and I[17] introduced an irely different method from that employed by ogh and Lindhard for determining the output of heart in man. We found by this method at the set that the output of blood from the heart in eral normal resting persons was of the order of litres per minute, with a correspondingly large put per beat, a value considerably higher than vious estimates. In developing the method ther, Haldane and I[18] made a number of careful ervations on myself during conditions varying m complete rest to moderately hard work. These wed that starting with an output of blood from the rt of about 7·5 litres per minute during rest the put varied roughly in proportion with the pulse- e as the metabolism rose up to a value represented the absorption of about 2 litres of oxygen per ute; the output of the heart per minute had reased to 2·5 times the resting value, while the rate oxygen consumption had risen to 8·5 times the ting value, and 64 per cent. of the oxygen available he arterial blood had disappeared by the time the ous blood entered the lungs instead of 19 per cent., value found during rest. Beyond this point we e unable to apply our method. There was no rease in the amplitude of the heart beat, the reased circulation rate being attributable merely to the rise in pulse-rate. On the other hand, we did obtain evidence, though it was less reliable, that in two subjects increase of metabolism was associated not only with a rise in pulse-rate but also with an increased amplitude of beat.

It seemed to us that there was a fallacy underlying the nitrous oxide method which was very difficult to avoid, and that though Krogh and Lindhard's observations might be right in general sense, their actual figures could not be accepted with complete confidence. So far as our own observations went an increase in the venous return to the heart might be dealt with either by an increase in the pulse-rate alone, as it was in my case, or by a combination of this with increased amplitude of beat. This difference in behaviour may perhaps depend on individual peculiarities; it may even be shown by the same individual at different times according to the circumstances of the moment, for we know that nervousness or mental excitement can cause a marked acceleration of the pulse-rate even in the resting person, and, unless there is at the same time a material alteration in the metabolism, it is difficult to believe that this is accompanied by any significant change in the output of the heart, and a diminution of the amplitude of beat in association with the increased pulse-rate seems a more reasonable assumption.

Had it been possible to apply our method for the measurement of the output of the heart during the performance of still heavier work, it is quite possible that I, too, might have shown a greater systolic discharge per beat. In extremely heavy work the output of the heart must be very greatly increased. A. V. Hill, Long, and Lupton have shown that an actual absorption of oxygen of 4 litres per minute can be attained by an athlete when breathing air, and of more than 5 litres a minute when breathing oxygen, and by a simple calculation they prove[19] that an output from the heart of not less than 30 to 40 litres per minute would be essential to convey this oxygen to the tissues which use it. With a pulse-rate of 180 per minute this would involve a systolic discharge of the order of 200 c.cm. per beat, a figure which is considerably in excess of the highest values hitherto recorded for rest. These figures for the output of the heart during severe work may seem enormous, but there is no escape from this conclusion, and it is not surprising that the aorta which has on occasions to transmit so large a volume has an internal diameter of an inch at its origin.

More recently a new method of determining the output of the heart has been suggested by Yandell Henderson and Haggard. This method depends, as does the nitrous oxide method, on the determination of the rate at which a gas which does not combine with any of the constituents of the blood is carried away in solution in the blood when a certain definite concentration of the gas in question is maintained in the alveolar air in the lungs. By the choice of ethyl iodide for this purpose it has been possible to avoid the fallacy which appears to underlie the nitrous oxide method, and one great advantage has been gained—namely, that of simplicity. During rest Henderson and Haggard find a comparatively large output from the heart per minute, just as Miss Christiansen, Haldane, and I did; indeed their figures are, on the whole, distinctly higher than ours, but they differ from Haldane and myself in their conclusions as to the results of muscular work of moderate severity. The contrast is clearly shown in Table I., where I have arranged the different experiments in the order of the recorded oxygen consumptions per minute.

It will be seen that the output of the heart increases in our experiments fairly gradually until a value of 18·7 litres per minute is reached, when the oxygen consumption has mounted to about 2 litres per minute. On the other hand, Henderson and Haggard's results show a surprisingly high figure for the output of the heart with but a moderate increase in the metabolism. Indeed, when the oxygen consumption per minute rises to about 2000 c.cm., the output of

the heart appears from their records to attain a value of 25 to 30 litres per minute, and yet in the last case shown in the table the extremely high oxygen consumption of 4600 c.cm. per minute demands no further increase in the output of the heart. The subjects marked with an asterisk in the table were all highly-trained athletes, who either rowed or played football

for Yale University. From some other observations made by Henderson and Haggard [21] we learn that B. M. S., who, as shown above, had an output of the heart of 18 litres per minute when doing work on the bicycle ergometer demanding an oxygen consumption of only 1200 c.cm. per minute, was capable of maintaining a rate of oxygen consumption of more than 3·5 litres per minute when working for several minutes on the rowing machine, while A. N. W., who could attain a similar figure on the rowing machine, had an output of blood from the heart of no less than 26·2 litres per minute when consuming 2000 c.cm. of oxygen per minute on the bicycle ergometer.

It is not easy to believe that when work is done of so moderate a character as that represented by an oxygen consumption of 2 litres per minute the output of the heart is really increased, as the figures seem to show, to a value which cannot be very far from the maximum of which the organ is capable; if the figures are true it would appear that little further accommodation is possible by alteration in the output of the heart to account for the high oxygen consumptions of 3 to 4 litres per minute, which we know can be kept up by athletes for considerable periods during strenuous exertion. We should have to face, too, another difficulty, for the extra oxygen would have to be obtained mainly by abstracting more oxygen from each unit of blood as it passes through the muscles, and this would be accompanied by a proportional and, as will be obvious, a very serious rise in local CO_2 pressure. I have already pointed out that there are objections to the idea that the local hydrogen-ion concentration can be considerably varied with impunity. The venous blood which enters the lungs from the right side of the heart has, it is true, a much larger oxygen deficit and CO_2 content during work than it has during rest, but this in itself is no indication that the variation represents a similar change in the gas-content of the blood traversing the muscles. The venous blood entering the lungs is a mixture of blood from different parts of the body, some more venous in character and some less. So far as can be judged from the available evidence, the blood returning from the muscles has a very low oxygen and high CO_2 content even during rest, and Haldane and I thought that the facts c be more reasonably explained by the assump that no great change occurs during work in the content of the blood leaving the active mus but that this highly venous blood returning in gr increased quantity to the right side of the h now forms a far higher proportion of the mixed ve blood entering the lungs than it did during rest.

The validity of Henderson and Haggard's me depends on the assumption that ethyl iodide solution in the blood stream in the lungs is decomp so completely in its passage through the tissues practically none returns to the lungs, and their ex mental evidence seemed to warrant this assump Yet Moore, Hamilton, and Kinsman,[22] as we Starr and Gamble [23] assert that ethyl iodide is fully decomposed in this way, but that ma amounts are to be found in the venous blood this is so, and the point ought not to be dif to settle definitely, the method as practised at pr must prove fallacious.

In any case there is, I think, another se criticism which can be brought against Hend and Haggard. An essential feature in their me is an estimation of the mean concentration of iodide in the alveolar air, and the sample of alv air which they use for this purpose is obtaine collecting the last few c.cm. of air expired in a nu of consecutive normal breaths. I pointed out i preceding lecture that Krogh and Lindhard some years ago that if alveolar samples are coll by the Haldane-Priestley method the CO_2 centrations found will be unduly high owing to the occupied in giving the forced expirations requir this method. The discrepancy may be imma during rest, but it will become significant during muscular work when the rate of blood flow th the lungs and the amount of CO_2 expelled int alveolar air are greatly increased. It seems t that this criticism must apply even with gr force to a method in which the alveolar sample taken only at the extreme end of the expira and if so, it will mean that the ethyl iodide conce tions found in the alveolar air will not repr the true mean concentration, but some value defi below this. The estimate of the blood flow th the lungs and of the output of the heart will t fore be too high. Provided that the subject is s quiet and that the depth of respiration is no shallow, I am quite prepared to believe that samples taken as Henderson and Haggard have may agree closely with those obtained by the Hal Priestley method, but I cannot help feeling during muscular work of not too great severit average of two Haldane-Priestley samples correctly at the end of inspiration and of expir will give a value which, though somewhat h in CO_2 or lower in ethyl iodide than the true me the alveolar air, will be more nearly correct than obtained by Henderson and Haggard. This may help to explain the fact that Henderson Haggard have found much higher figures fo output of blood from the heart during mod muscular work than Haldane and I did. Pe we might even trace to the same cause the cu fact shown by the ethyl iodide method tha output of the heart is, as will be seen from the fi in Table II., apparently greater when lying than when sitting or standing still. Haldane I certainly saw no indication of this in my own It may be that if the breathing slows down and de when lying down, as is often the case, the Hende Haggard samples taken at the end of expi only may again give values differing to a ma extent from the true mean. I admit that the m devised by Miss Christiansen, Haldane, and n is not free from error, but it seems to me wh review the other methods which are available a moment that it ought, on the whole, to afford r which most closely approach the truth. We have to face the criticism that the alveolar sa on which we depend for our estimate of the

centration in the arterial blood, which forms an ntial point in the argument, are somewhat too n during work, but so far as I can judge the dis- ancy during moderate work is probably not very t, though it will tend to make our calculated ies for the output of the heart a little too great he work gets harder.

There may be controversy as to the relative parts yed by variations of pulse-rate and amplitude of

t in the normal response of the heart during rcise, but there is no difference of opinion as to the ity of the heart to deal effectively with a great ease in the amount of blood which may reach it ough the veins and pump it on into the arteries.

Arterial Blood Pressure during Muscular Work.

When once the heart has begun to force on into the erial system the increased quantity of venous od that reaches it through the veins, the general ulation-rate will be increased and the supply of od to the active muscles with their dilated vessels be ensured. The arterial blood pressure is ermined at any moment by the output of the rt and the prevailing arterial resistance. During scular work the blood-vessels are dilated in the ve muscles and compensatory constriction of sels in the inactive parts of the body reduces the l volume of blood retained in these places and llows for the proper filling of the dilated vessels. ually the arterial blood pressure rises considerably ing muscular work as is well known, and Dr. D. Paterson and I, in following in ourselves the ages of blood pressure which take place on passing a rest into activity, have found that a systolic od pressure of 200 mm. of mercury can be quickly hed when doing work of moderate severity. The ease of arterial blood pressure will no doubt help maintain the requisite flow of blood through the ns in which compensatory constriction of blood- els has occurred. In spite of this, however, it seem from the observations of Haldane and elf, as well as those of Pembrey, that during cular activity the rate of blood flow through the tively inactive parts of the body is actually inished. This fact need not, however, conflict the postulate that the blood flow must be roximately proportional to the metabolism, for it quite likely the metabolism of the parts ted—alimentary canal, glands, &c.—may also be nished for the time being.

ull accommodation of the circulation, and of the iration too, to meet the requirements of muscular cise is by no means instantaneous. It takes time, gh not very long, for a balance to be struck even e work done is but moderate, and stimulation he nervous centres involved in the adjustment h may be attributed to psychic effects connected the transition from rest to work appears some- s to accelerate the early stages. When once the stment is established, however, it will persist so as the muscular work remains steady. When the stops we may anticipate a reverse series of changes to that which occurs on the commencement of exercise. With the reduction in the metabolism the capillaries in the muscles will diminish in calibre, the previous compensatory constriction of blood-vessels elsewhere in the body will give place to dilatation, the venous return to the heart will be slowed down, and with the diminution of the stimulation responsible for the Bainbridge reflex the pulse-rate will decrease, the output of the heart will become smaller, and the arterial blood pressure will fall. Observations by Lindhard [24] and by Lythgoe and Pereira [25] point to a rapid diminution of the general circulation-rate when muscular exercise stops. It is possible that as the stimulus which evoked the accelerator reflex diminishes in the earlier stages of rest, the antagonistic depressor reflex which depends on the passage of afferent impulses up to the branches of the vagus connected with the left ventricle and aorta [26] may come into play and help to hasten the return of the pulse-rate and arterial blood pressure to normal values.

As in the case of the regulation of the breathing coördination of the circulation with increase in muscular activity seems to be attained by the coöperation of chemical and nervous factors. In the chemical changes resulting directly from alteration in the metabolism and in reflexes, whether peripheral or central, initiated by stimuli originating in the active muscles we can, I believe, find the cause not only of local vascular dilatation but also of compensatory vasoconstriction. The heart responds automatically to the resultant increased venous return owing to the accelerator reflex to which it is subject and to its own potential capacity for increasing its amplitude of beat. The correct adjustment of the whole circulation is, in fact, set by those peripheral organs whose activity happens to change, but in obtaining their own appropriate supply of blood the rest of the body does not suffer.

This sketch which I have attempted to draw of the factors concerned in the regulation of the circulation is but rough and incomplete. Far more information must, I fear, be obtained before we can hope to appreciate in full the delicacy and subtlety of adjustment of blood flow to meet the ever-changing variations in activity of the muscles, organs, and glands, indeed of every part of the body, which occur in normal everyday life, but until we can do this we cannot claim to understand properly the circulation of the blood.

THE PREPARATION OF PATIENTS FOR OPERATION.

BY W. E. M. MITCHELL, *M.C.*, M.B., B.S. LOND., F.R.C.S. ENG.,
CHIEF ASSISTANT TO A SURGICAL UNIT, ST. BARTHOLOMEW'S HOSPITAL.

WITH the passage of time and the accumulation of experience the methods adopted in preparing patients for the ordeal of a surgical operation have undergone radical alteration. Advances in surgical technique and greater accuracy of diagnosis have gone hand in hand with a crystallisation of ideas on the most satisfactory preoperative preparation of the patient.

Objections to the Use of Castor Oil.

Formerly purgation and starvation, both as complete as possible, were the order of the day, the paramount consideration in the mind of the surgeon being the emptiness of the whole alimentary tract. The usual purgative was castor oil in full dose, and this drug succeeded in irritating the intestine to such an extent that the bowels acted frequently and forcibly. Oil was given the night before the day of operation, and the patient's rest and sleep were disturbed by numerous and insistent calls to stool.

The mode of action of castor oil in the intestine is well known. It acts as a purgative in virtue of its transformation in the duodenum into ricinoleic acid. This substance is a strong intestinal irritant and very effectively stimulates peristalsis in the gut as it passes through it. The object aimed at in giving the drug—namely, the complete evacuation of the bowel—is attained with more certainty with castor oil than with any other of the common purgatives; but the advantages and disadvantages of such treatment demand careful consideration. The advantages of drastic purging of the intestinal tract are few in number, and are confined to cases where it is desirable to empty the colon completely and to avoid a movement of the bowels for as long as possible. Such cases are those requiring operation on the anus and anal canal, and especially those for the cure of hæmorrhoids. In these special circumstances castor oil empties the intestine admirably, and the constipation, which is its well-known sequel, effectively guards against bowel movement for several days.

The first disadvantage of castor oil in the preparation of a patient for operation is its strongly irritant nature. The ricinoleic acid stings the intestinal mucosa and musculature so venomously that the gut is irritated, reddened, swollen, and exhausted by the insult. The intestine is empty and collapsed after such treatment, but it is not in the best condition to withstand the mechanical interference of the surgeon. Such irritation leaves it in a condition most unsuitable for intestinal surgery.

The second disadvantage is the most serious; it is the inertia of the intestinal musculature which follows the irritation and overaction caused by the oil. This inertia is, I believe, one of the most fruitful sources of ileus after abdominal operations. The simplest laparotomy, however clean the incision and however gentle the manipulations, must result in some disturbance of the normal peristalsis in the intestine. Two factors are concerned in producing this disturbance; one, the mechanical interference with the gut itself by handling, incising, suturing, "packing-off," &c.; the other, the immobility of the abdominal wall which follows the closing of the incision. This immobility is a result of nature's protective reflex, which keeps all the muscles on guard against the smallest movement, and also of the firm bandaging of the whole abdomen. If to these two factors tending to inhibit normal peristalsis and avoidable in any laparotomy be added the intestinal inertia consequent on the administration of castor oil, then the risk of abdominal distension after the operation is very materially increased. It wil conceded generally that tympanites is probably most frequent cause of discomfort after laparotc and while it is usually transient and may give to but little discomfort, yet it sometimes jeopard the patient's chances of recovery. Any metho avoiding this common and distressing postopera complication is greatly to be desired, and the step towards such a method is the avoidance of severe intestinal irritation produced by castor oi

The last disadvantage of castor oil—and thi especially great if it be given the night before op tion—is its interference with the patient's rest. ensuring of sleep and rest as undisturbed as pos is recognised to be one of the best prophyla against shock. Where is the surgeon who has remarked the great power of resistance to sh displayed by the phlegmatic type of patient wh less excited about his operation than the surgeon performs it? Such a subject will come through ordeal with little lowering of his blood press compared with that which might occur in a ner patient in the same circumstances. It is sure matter of common observation that the reserv "vital force" is built up by refreshing sleep b than by any other single agency. I submit that disturbance of sleep incidental to the use of l doses of castor oil on the night before operation menace to the patient's powers of resistance and o to be avoided.

Not content with the violent purgation proc with this drug, many surgeons demand further their patients be given an enema on the oper morning. The object of this, apparently, is to er the large intestine, and to avoid the possibilit the castor oil continuing to force the bowels t right up to the hour of operation, and perhaps o operating table. To some patients the giving c enema is in itself a weakening measure, and it least advisable to avoid anything which may tend to deplete a patient's strength on the mo of the operation day. It must have been experience of some that a nurse has wakened a pa from sleep in the very early hours of the mornir administer an enema, and that to one who has disturbed most of the night, and sadly needs sleep that may be secured in the intervals of co cramps. Surely the night preceding operation ca relieved of such terrors as these.

It may be said in extenuation of the castc purge that for intestinal anastomosis it is nece to have the bowel empty, and therefore that c oil supplies an important need. In answer to a statement I would say that:—

(*a*) Emptiness of the gut is not a necessary con for satisfactory intestinal anastomosis; the resourc surgery are surely sufficient to guard against the esca intestinal contents when a part of the bowel is incised

(*b*) The collapsed and contracted state of the bowel r anastomosis more difficult than it need be, and end-t anastomosis may be made very difficult by such a st the intestine.

(*c*) The anastomosis of loops of bowel irritated contracted, besides being difficult at the time, is liable to be followed by stenosis of the aperture than such anastomosis in normal bowel.

(*d*) The inertia of the gut following the hyperac caused by the oil is a menace to the functioning c stoma.

The disadvantages of such purgation in i abdominal operations have no counterbala advantages, and this preparative treatment is very generally supplanted by one more hu and enlightened.

Objection to Preoperative Starvation.

With reference to starvation before abdo operations, that too is becoming a relic of the p at any rate in the degree to which it was for practised. The withholding of food for 12 t hours, and the giving of nothing but water, v rigorous régime and one which now has litt be said in its favour. The old idea of admitti

ds into the alimentary tract within half a day of operation, and the removal of all intestinal tents already there, apparently was designed not y to produce the best possible condition of the ient and his viscera for surgical interference, but) to guard against postoperative distension. In s latter object it usually failed as signally as it in the former, chiefly, as has been said above, on ount of the constipating effect of castor oil; but) because of the absence of the normal stimulus to istalsis—namely, the intestinal contents.

The strongest argument against the preoperative rvation of a patient is the fact that such with-ding of food predisposes to acidosis, or the ering of the alkali reserve in the blood. This uel is the more liable to follow in children, ticularly in those cases where a septic process is work, and when chloroform or ether, but especially former, is used as the anæsthetic. It is said that n the mild attacks of vomiting that occur after st laparotomies are due to a slight degree of losis. It is my belief that this vomiting is entuated, not relieved, by preliminary starvation too long a time.

Modern Preoperative Methods.

Having criticised the older methods of preparation, wish now to outline the means that are being pted more and more in the routine preparation of ients for laparotomy, and to refer incidentally a few of the special methods required in some cial cases.

The examination of the cardiovascular system, lungs, the nervous system, the urine, and the mation of the efficiency of the renal function, can lly be termed preparation for operation. They to be regarded more properly as part of the tine examination from whose data, together with record of his history, the diagnosis of the patient's plaint has been made. For this reason it has n assumed here that these investigations have n carried out in the complete examination of the ent before operation is contemplated.

reoperative measures may vary somewhat to t the needs of certain special organs, such as liver or kidney, when these are diseased, or to viate certain troubles due to obstruction in the ientary tract. For the majority of abdominal rations, however, and for all operations on other s of the body, when general anæsthesia is used, following scheme of preparation is advocated.

The removal of any sources of focal infection—e.g., ic teeth, tonsils, &c.

The ensuring of a free daily evacuation of the bowels n adequate dose of paraffinum liq. night and morning.

A course of tonic treatment with fresh air, exercise r as possible, and suitable food. These three desiderata have been achieved in some cases by treatment rgone before the operation in view was recommended; ther cases a period of one week is usually sufficient to v these procedures to be carried out.

Admission to the nursing home or hospital ought to be ater than 6 P.M. on the day before operation.

The patient then has a warm bath and goes to bed.

The anæsthetist and the surgeon visit the patient in oom, and sees that the nurse understands the technique reparation for the operation next morning.

The patient's supper consists of a light meal such as , boiled fish or chicken, with plain sauce, spinach, er, toast and plain biscuit, jelly. No potatoes, fresh d, cheese, strong tea, or coffee. Unrestricted fluids to s. Alcohol only if specially ordered by surgeon.

The skin of the whole anterior abdominal wall and as to be shaved, washed with ether, and covered with rile towel.

Later in the evening when the patient is feeling sleepy given a hot drink of ovaltine, or Horlick's malted milk.

. A mild laxative such as that to which the patient is accustomed—e.g., paraffinum liq., senna, liquorice—ministered in the dose which he knows to be effective r normal circumstances.

. Teeth are scrubbed thoroughly with a new tooth-h and an antiseptic tooth-paste—e.g., euthymol.

. Lights out 10.30 P.M. or at discretion of nurse.

. Night nurse ensures a good night's rest. Gives hot s, &c., but after 2 A.M. only water or sweetened lemonade.

14. Sleep on no account to be disturbed till 7 o'clock next morning.

15. Patient is given a glass of hot water to drink on waking.

16. Teeth are scrubbed as before. Toilet completed, (including shave).

17. Enema is administered only if no result from laxative by 7.30 A.M.

18. 8.30 A.M., hypodermic injection, atropine gr. 1/100, morphine gr. 1/6.

19. Bladder emptied. If not, note is sent with patient to theatre with time of last micturition indicated.

20. Operation 9 A.M.

It will be seen that the above scheme aims at presenting the patient to the surgeon on the operating table with his mind well rested by refreshing sleep, and his nervous energy conserved by the absence of excitement and long suspense before the early morning operation. His tissues are not desiccated by excessive excretion of fluids, the result of perspiration, increased frequency of micturition, and even diarrhœa which often follow nervous excitement. The patient comes to operation with his tissues adequately supplied with water, his food reserves in their usual state, his metabolism adjusted as perfectly as may be, and his intestines working normally—in short, in such a condition of fitness that the shock of operation may affect him as little as possible.

Risks of Focal Sepsis.

The attention to septic foci in the mouth and nose cannot be too meticulous, and it is nothing less than a surgical crime to perform an operation (other than an emergency one) with general anæsthesia in the presence of frank oral or nasal sepsis. This is said on account of the risk of pneumonia supervening in such cases. When dealing with what Mr. A. J. Walton has named the "surgical dyspepsias," the medical attendant doubtless will have eliminated any focus of infection that he may have been able to discover; on the other hand, he may not have thought it worth while to treat dental sepsis in a patient awaiting such an operation as that for the radical cure of hernia. It is, however, to be insisted on that the risk from the anæsthetic is materially increased when it is administered through a cavity in which virulent pathogenic organisms abound.

Special Precautions.

Before laparotomies, in the course of which it is expected to open the stomach or small intestine, some surgeons give only sterilised milk and water for one or two days before the operation. This would appear to be unnecessarily fastidious, because the chyme in the duodenum and upper jejunum is to be regarded as sterile under ordinary conditions, and the stomach contents, if any, are practically so after the routine treatment described above.

In cases of pyloric stenosis the stomach may empty so incompletely that a mass of decomposing foodstuffs is left in it even after the consumption of soft foods only. In such a case it is wise to wash the stomach out the night before operation, and afterwards to give fluids only in small quantities.

Before operations on the biliary apparatus, the preparation of the patient demands peculiar attention, and the nature of the preoperative treatment varies with the presence or absence of jaundice. It is wise to preface all operations on the biliary tract with the administration of hexamine, gr. 10, t.d.s., for a week at least. The object of this is to disinfect the bile passages. In the presence of jaundice two risks must be guarded against before operation is undertaken. One is hæmorrhage on account of the lengthened coagulation time of the blood in these patients, the other is the relative hepatic insufficiency likely to have been produced by biliary obstruction. The risk of hæmorrhage should be anticipated by the intravenous injection of calcium chloride, 5 c.cm. of 10 per cent. solution, once daily for three days, taking great care that the whole of the solution is delivered within the vein and that none escapes into the subcutaneous tissue. Hepatic insufficiency is guarded against by the administration of glucose to restore

the glycogen reserve, to combat the tendency to acidosis, and to spare the liver the strain of dealing with large quantities of amino acids. Glucose is most easily administered per rectum, 10 drachms glucose and 1 drachm bicarbonate of soda in a pint of water.

Where chronic obstruction is present in the colon, this may be relieved by preoperative preparation with enemas and the feeding of suitable food to the patient. Such intelligent treatment is likely, if successful, to remove much of the risk of operation for the permanent relief of colonic obstruction. When unsuccessful, these measures must be supplemented by a preliminary operation to relieve the obstruction before anything further is attempted in these cases.

The preparation of patients for operation upon the genito-urinary system demands special consideration, and cannot be discussed within the compass of this article.

In surgical emergencies the urgency of the patient's condition is such that any prolonged preparation before operation is out of the question. There are, however, one or two points in the preoperative treatment of acute cases which are calculated to increase the chances of success. The onset of an abdominal catastrophe, such as the perforation of a viscus or acute pancreatitis, gives rise to immediate shock and prostration, so great that the patient is a bad "operation risk" during the first hour or so after the event. Such a patient is best treated by a full dose of morphia after the diagnosis has been made, and by being kept warm in bed between blankets with hot-water bottles. The initial severe shock passes off in an hour or so under such treatment, and the patient is left in a condition better adapted to withstand the further shock of operation.

In acute appendicitis, especially in children, the hour or two that may have to elapse before operation is most usefully spent in the administration of glucose per rectum. This is a precautionary measure against delayed anæsthetic poisoning in these cases susceptible to this dire event. Acidosis is already present in a large proportion of them; for they have eaten nothing for some time before operation, and an acute septic process is at work. The number of cases of acute appendicitis in children showing a positive Rothera's test for acetone bodies in the urine must be a large proportion of the total. The writer knows of no statistics in support of this statement; but his experience is that the test is positive in the majority of such cases.

The washing out of the stomach in cases of acute intestinal obstruction is a preoperative measure which is time-honoured. Its efficacy, however, is doubtful, because the stomach usually refills with the dark regurgitating fluid as quickly as it can be emptied. For this reason stomach lavage has not established its place in preoperative preparation of patients in, or approaching, the stage of fæculent vomiting from intestinal obstruction. In such cases the use of spinal or regional anæsthesia seems to hold out better hope of success than does general anæsthesia with its attendant risks of vomiting and aspiration of foul liquid into the lungs.

The smooth convalescence of many patients after emergency operations before which routine purging and starvation were impossible to carry out first attracted the writer's attention to the subject of this article. Doubt as to the wisdom of the old methods of preparation was aroused by noting the frequent occurrence of tympanites after simple laparotomies. The scheme outlined in this paper was evolved to effect the changes which were considered desirable.

It must be admitted that the majority of patients undergoing operations with general anæsthesia convalesce well whatever their preoperative preparation. It cannot be gainsaid, however, that careful attention to the simple points mentioned in the scheme above has the most soothing and beneficial effect, and that patients recuperate the better for it.

This good effect, moreover, is so great as to be well worth the trouble and care taken in inducing it. It is in cases where the peritoneal cavit opened that the benefits of such careful prepara are most manifest; the advantages are but less remarkable in cases where the operation i other parts of the body.

THE RELATION OF FUNICULITIS TO HYDROCE IN EGYPT.

BY ALI BEY IBRAHIM, M.B.E.,

SENIOR SURGEON TO KASR-EL-AINY HOSPITAL; PROFESSO SURGERY, FACULTY OF MEDICINE, CAIRO, EGYPT.

CELLULITIS of the spermatic cord has long recognised as a fairly common affection in the In Egypt F. C. Madden [1] drew attention to the dition in 1907. In Ceylon, where it had for been known, A. Castellani [2] began to invest it in 1904. In 1908 he described it more fully, g it the name of endemic funiculitis.[3] In 1909 I Coutts,[4] at Kasr-el-Ainy Hospital, made a com study of the condition, and published clinical bacteriological particulars about it.

Incidence.

During the four years 1921–24, 105 cases admitted to Kasr-el-Ainy Hospital for this comp and about double this number were treated as patients. These figures, however, represent the s or moderately severe cases which form a very percentage of the total incidence of the disease. commonest form is so mild, causes so little i venience, and is of so short a duration, that th hospital class of patient does not usually seek a for it. In the better-class patients seen in pr practice one meets with two or more cases for one case seen in hospital.

It occurs more often in April, May, and June, th it is present all the year round. It is a disea young men of 15 to 30 years. I have seen it in a man of 60, but never in a child. It is us unilateral, but may affect both sides, either simul ously or separately; and the attacks are us repeated at variable intervals.

Ætiology.

Castellani believes the condition to be a fi disease with a superadded streptococcal infe He found in the blood of several cases a filaria si to, but, in his opinion, distinct from, *Filaria ban* Coutts succeeded in growing a Gram-positive streptococcus from the inflamed cord as well as granular patches in the urethra. But alth the short streptococci can be demonstrated by and culture in most cases of this disease, filar blood films taken at night or in day-time can be found. As a routine, the examination of blo filariæ was not done on cases of funiculitis adm to Kasr-el-Ainy Hospital, but in the last 12 examined filariæ were found in two only.

Varieties.

For practical purposes three varieties of the d may be described: (1) gangrenous, (2) suppurativ (3) non-suppurative. The non-suppurative variet further be subdivided into a severe and a mild The suppurative variety is decidedly less co than the non-suppurative. It is interesting to however, that, whereas only 3 of 84 cases se me in private practice were of the suppurative va yet 70 per cent. of the cases admitted to Kasr-el Hospital were of that variety. The non-suppu variety does not cause enough general and symptoms to drive the lower-class patient to ho

(1) In the *gangrenous type* the inflammation severe that all the vessels of the cord become t

[1] THE LANCET, 1907, i., 505.
[2] Manual of Tropical Medicine, second edition.
[3] THE LANCET, 1908, ii., 15. [4] Ibid., 1909, i., 227.

osed, the blood-supply is cut off, and the testicle nd a long piece of the cord become gangrenous. he onset is sudden and the patient becomes quickly nd profoundly septicæmic and dies in two or three ays, even in spite of early interference. Luckily nough it is the rarest of all forms.

2. *Acute suppurative funiculitis* usually starts ıddenly with rigors, vomiting, and fever. Conɔmitantly the spermatic cord becomes painful, ɔnder, and greatly swollen, and rapildy goes on to ıppuration, which, in the severer type of case, may ɔread to the pelvic and retroperitoneal cellular ssues. The testicle is usually only slightly enlarged ıough extremely tender, and, as a rule, there is ;tle or no effusion in the tunica vaginalis at this age of the disease. As the case advances the general ɔndition goes from bad to worse; the tongue is ırred and dry and the patient looks profoundly ɔptic. There is no tendency to spontaneous recovery ıd, if operative interference is delayed, or sometmes in spite of operation, septicæmia or septicoɔæmia sets in. Abscesses may form all over the body, ıe pyæmia selecting especially the knee-joint. In ɔery case the same diplo-streptococcus could be ɔmonstrated.

The structures of the cord are covered and matted gether with lymph exudate and bathed in pus. ıe blood-vessels are clogged with septic thrombi. ıe vas deferens is actually inflamed and pus can ɔ squeezed out of its lumen. Microscopically the cture is one of acute inflammation with, however, marked increase of the eosinophile element in the llular infiltration. Cultures from the exudate in e tunica vaginalis are always negative, but from e cord itself the diplococcus can always be grown.

The following is a typical leucocyte count of one these cases: total, 19,750; polymorphs, 62 per nt.; lymphocytes, 18 per cent.; eosinophiles, per cent.

3. *Acute Non-suppurative Funiculitis.*—This is the ost common variety of the disease; it has long en recognised in Egypt, being usually described as rombosis of the spermatic cord. Only comparaɔely recently has it been recognised as a variety of demic funiculitis. Though the onset is as sudden in the suppurative variety, constitutional symptoms not usually amount to more than a slight degree fever. There is a dragging pain in the groin and moderately hard and tender swelling on the affected le. The structures of the cord are matted together. ıe veins can be felt thrombosed and the corresponding ididymis is slightly tender. But neither the general r local condition is, as a rule, severe enough to ıd the patient to bed or keep him from his daily ɔrk. Pain and swelling may be so insignificant often to pass unnoticed by any but an observant hypochondriac patient. The condition is not ɔgressive. Slow absorption begins at about the end the first week, so that by the end of the second or ird week the infiltration has nearly cleared up, ɔving the cord only slightly more fibrous than fore. The severer type of this variety of the ɛase is rarely met with. In it both general and ıl symptoms are greatly exaggerated, and, though the cord itself actual suppuration is not detected, ıæmic symptoms may supervene, and the same ganisms can then be found in a pyæmic joint or scess elsewhere.

Pathology.

Investigation of this non-suppurative funiculitis is ıde difficult by the fact that the disease is not fatal d operative interference is not indicated, so that ither a post-mortem nor an ante-mortem examinaɔn of sections or specimens is easy. But I was lucky ɔugh to get the consent of 12 patients for an explorayy operation; and, in some cases, actually did a rtial excision of the cord (minus the vas) for pathoɔical examination in the different stages of the ɛase. Macroscopically, the cord looks fibrous and ɔ structures are matted together and cut like cheese. rombosis is present in all or most of the vessels, d from some of the veins a bead of pus can sometimes be expressed, though there are no localised abscesses in the cord. In fact, the histology of this condition resembles that of the suppurative variety (acute inflammation with marked eosinophile infiltration, &c.), except that suppuration is not present. It is noteworthy that in cases where pus was actually demonstrated inside the veins healing took place by first intention. In this variety culture from the cord sometimes fails.

Of the 12 cases, 4 were examined at the end of the first week, 4 at the end of the second, and 4 at the end of the third.

First week.—The microscopical picture is typical of phlebitis and periphlebitis together with lymphangitis and cellular infiltration of the cellular tissue in which the eosinophiles predominated.

Second week.—Clot that filled up the vein shows signs of the disintegration and organisation and the formation of fibrocellular tissue in other parts of the cord.

Third week.—Some veins are obliterated; others have thickened fibrosed walls and patient lumen simulating arteries to the naked eye. The rest of the cord (excluding the arteries and vas) is transformed into fibrous tissue in which no lymphatics can be detected.

There is no marked leucocytosis, but the relative number of eosinophile cells in the blood ranges between 6 and 20 per cent. Examination of the cord after one or more of these attacks reveals sclerosis, fibrous tissue predominating round and between the constitutents of the cord as well as in the adventitia of the veins. The walls of the latter look, to the naked eye, like thick arterial walls, and the lumen in some of them is found obliterated.

Sequelæ.

The above is the clinical and pathological picture of endemic funiculitis as seen in Egypt. But what is the further history of the cases? I was fortunate enough to discover it in some of my patients seven years ago, and since then have tried to follow up all such cases. I have repeatedly found that, either during an attack, towards its end, as absorption is taking place, or sometimes even after all signs and symptoms of funiculitis have cleared up, a hydrocele of the tunica vaginalis gradually formed on the affected side. A single attack of mild funiculitis may not result in a hydrocele, but further attacks always produce hydrocele, or enlarge a pre-existing one. Such hydroceles persist and usually go on enlarging after the attacks and are not to be compared with the type of inflammatory and temporary hydrocele met with, for instance, in gonorrhœal epididymitis, which tends to become absorbed as the inflammation subsides.

I now look upon funiculitis as the main, if not the only, cause of the hydroceles so prevalent in Egypt, and up to now labelled idiopathic. In four years 424 cases of hydrocele were admitted to Kasr-el-Ainy Hospital for treatment and more than 730 were tapped in the out-patient department. Of these a negligible percentage were secondary to orchitis, whether traumatic, syphilitic, gonorrhœal, or otherwise; but the huge majority were of the so-called idiopathic variety. Loosely fitting clothes, donkey-riding, relaxation of the scrotum from heat, and excessive coitus are among the factors which have from time to time been suggested as causes of hydrocele in Egypt. Yet hydrocele is as common in the trousered effendi as in the wide-robed sheikh, in the town-dweller as in the rural fellah, and in the Upper as in the Lower Egyptian. And it will be found that all such theories fall to the ground on investigating the histories and habits of any large number of cases. In thousands of cases of hydrocele all investigators have failed to find filariæ in the night blood; but it must be remembered that the same negative results have been obtained in elephantiasis during any but the acute stages of the disease.

In my opinion it is quite justifiable to consider the effusion in the tunica vaginalis as the results of the permanent obstruction of the testicular lymphatic drainage produced by one or more attacks of funiculitis in the same way as elephantiasis is the result of the

repeated attacks of lymphangitis that occur in filariasis. The fibrous thickening of the spermatic cord so constantly seen when operating on hydroceles and which has always been considered to be due to the dragging weight of the hydrocele is, in my opinion, nothing but the permanent effect of a previous attack (or attacks) of funiculitis. I have examined sections through the spermatic cords of three or four cases of hydrocele taken at random, and have found in each of them the same increase of fibrous tissue and the same thickening of the adventitia of the veins as is found in the non-suppurative cases of funiculitis after the acute symptoms have subsided (vide supra).

Conclusions.

(1) Hydrocele is common in countries where funiculitis is prevalent. (2) Funiculitis exists in Egypt to a much greater extent than one is led to believe by analysing the admissions to a free hospital. (3) It occurs in two forms—a severe form ending in suppuration and a milder form ending in absorption. (4) There is a great similarity between funiculitis and the attacks of lymphangitis met with in tropical elephantiasis, the underlying cause being probably a filaria, and the exciting cause a form of streptococcus. (5) The lymphatic and venous obstruction resulting from these attacks results in the formation of the so-called idiopathic hydrocele, which therefore corresponds to the subcutaneous lymphatic œdema in elephantiasis.

TWO CASES OF DIABETIC GANGRENE TREATED BY CONSERVATIVE SURGICAL MEASURES.

BY R. BROOKE, F.R.C.S. ENG.,
HON. ASSISTANT SURGEON, ROYAL WEST SUSSEX HOSPITAL.

UNTIL quite recently the operation of high amputation has been the treatment almost universally employed for diabetic gangrene. There is no doubt that a large number of successes have followed when this has been done, the patient subsequently remaining free from a recurrence for some considerable time. There is a distinct clinical type of the disease, the so-called "fulminating type," in which the spread of the gangrene is so rapid that operative measures cannot be undertaken, or in which, if high amputation is attempted, gangrene invariably and rapidly develops in the stump. Excluding altogether these comparatively few fulminating cases, there is no doubt that the number of recurrences after high amputation is at the present time much larger than it should be. The reason for this is not far to seek. It is largely due to prevarication with unnecessary delay before operative measures are adopted, when the time factor is one of extreme importance. The patient (and sometimes the surgeon) is reluctant to sacrifice such a large portion of the limb; and will temporise in the hope that an operation will prove unnecessary.

The use of insulin as a preoperative measure has done much to increase this delay; for with its use the progress of the gangrene may be checked for a time, thus too often leading to a sense of false security. A moment's consideration as to the underlying pathology of the disease—that it is a malnutrition phenomenon due essentially to changes in the blood-vessel walls of a permanent nature—must lead to the realisation that whatever the action of the insulin is, it is only a transient one, and cannot materially affect the course of the gangrene. Sooner or later the gangrene will recommence to spread, and the insulin will then cease to exert its usual beneficial effect. The amelioration of the local condition is of a temporary nature only, and does not warrant delay in amputation. Insulin, however, has its place in the operative treatment of diabetic gangrene. Used as a preoperative measure by rendering the patient sugar-free, or temporarily reducing his blood-sugar, it places him in a better position to withstand t anæsthetic and the operation itself.

Repeated trials have proved conclusively that l amputation by itself in the majority of cases will n prevent the spread of the gangrene. Recently at meeting of the Royal Society of Medicine so successes were reported following more conservati treatment in cases of senile gangrene and Raynau disease. The two most successful measures used we the operations of (1) periarterial sympathectom (2) ligature of the femoral vein. Profiting by t experience of others, and hoping to improve on th methods, in the two cases about to be described, combination of these two operations was used, a found to be of advantage. The reasons for using th combined operation will be discussed later. A br outline of the chief points in the history and treatme of the two cases is as follows.

Clinical Records.

L. M., aged 63 years; married, three children. Admitt to hospital on Dec. 12th, 1926, with a 12 years' history diabetes mellitus. She had had operations performed both eyes for cataract some years previously, and also g a history of numerous carbuncles. The patient was fou to be a well covered and robust individual. On the ri foot there was a patch of moist gangrene involving the fi second, and third toes, and extending well on to the ball the great toe, with surrounding œdema of the foot. T dorsalis pedis, plantar, and popliteal pulses were not palpa on the right leg, but were just palpable on the l Temperature 100°, pulse 100, respirations 20, urine spec gravity 1010, sugar 2·30 per cent., albumin a trace.

Treatment.—On the day of admission insulin, units three times a day, was given, and the urine became sugar-f almost immediately, remaining so throughout her stay hospital. Subsequently the dose of insulin was reduced f to 10, and later to 5 units per diem. She was kept o moderately strict diabetic diet. The foot was pla uncovered in a radiant heat bath. It smelt badly, and fr time to time exuded a small amount of foul sero-sanguine fluid. Two days after admission, as the gangrene and œdema were extending, an operation was performed.

Operation.—Under gas and oxygen an incision ab four inches long was made in the thigh. The femoral ves were exposed in Hunter's canal, and a periarterial sym thectomy performed. For a distance of two inches adventitia was stripped off the vessel, two minute muscu twigs being at the same time ligatured. No obvious pa or change in the vessel wall was noticed after removing adventitia (as reported by previous observers). The arte wall was found to be thickened, hard, and calcareous. femoral vein was then ligatured in two places and the wo closed.

At the end of the operation the leg was returned to radiant heat bath. On the next day—namely, Dec. 15t a remarkable change was noticed in the limb. The dors pedis, plantar, and popliteal pulses were not now palpable, but of distinctly greater volume than those of other limb. This increase in pulse volume has persis but in a much less marked degree, right up to the present ti Two days after the operation a line of demarcation was s at the edge of the gangrenous part. The area of gangr had not extended since the operation. On the third day œdema of the foot was less marked, and two weeks l had almost completely disappeared. Five weeks after operation the gangrenous area was quite dry and mummif and almost completely separated from the rest of the f being held to it by a few connective tissue fibres o The œdema had entirely disappeared. The temperature 98·6, pulse 72, and the respirations 20. The urine was su free with 5 units insulin daily. No pain was felt in diseased limb. The gangrenous part has since comple separated, and the patient is now up and about wearin surgical boot.

The second case is very similar to the first one.

CASE 2.—S. H., a baker, aged 59 years, had been tre for some years for diabetes, latterly with insulin on which had remained sugar-free for nearly a year. For some y he had had a painful corn on the ball of the second to the left foot. Three days before admission he noticed t the toe was discoloured and painful. At first he took li notice of it, but two days later the condition became m worse, and he presented himself at the hospital.

On admission (Jan. 30th, 1927): temperature 100·6°, pulse 100, respirations 20. There was well-marked m gangrene of the second, third, and fourth toes of the left f extending up on the dorsum of the foot for a distanc about half an inch, with an area of surrounding œd extending nearly to the ankle-joint. The heart, chest,

bdomen on examination were normal, urine specific gravity 005, reaction acid, sugar, albumin a trace.

Treatment.—The foot was at once placed in a radiant heat ath, and insulin, units 20, was given. The subsequent linical history of the case is very similar to that of the receding one. On the day following admission an operation as performed on the left foot; the artery and vein were xposed by a longitudinal incision over Hunter's canal. periarterial sympathectomy was performed with ligature f the femoral vein. Following the operation the dorsalis edis, plantar, and popliteal pulses were all temporarily xaggerated in volume on the side operated upon, and line of demarcation rapidly formed at the edge of the angrenous area.

On the tenth day after operation, at the man's own equest, in order that he could carry on with his business as oon as possible, an attempt was made to shorten the period f his stay in hospital. A Syme's amputation was performed. he wound healed by first intention, and the patient was ischarged with a very good, clean, and serviceable stump 4 days later. The urine remained sugar-free with 10 units f insulin daily.

Discussion.

There is good reason to believe that this combined peration of ligature of the femoral vein with sympa- nectomy of the artery is an improvement on either f these measures used by itself. One has only to xamine the hard, "gritty," calcareous walls of the lood-vessels in a case of diabetes of some years' uration to realise that, even when denuded of all aso-constrictor fibres, the power of dilatation of the essel distal to the site of operation must of necessity e impaired, owing to the mechanical obstacle caused y the degeneration of muscular tissues. Vaso- ilatation does occur after this operation—of that here is not the least doubt—and a form of active ongestion of the limb is thus produced. It is to this ctive congestion that the good effects of the treatment e attributed. Ligature of the vein produces a milar hyperæmia by passive congestion. When these two methods of active and passive congestion of the limb are combined a summation effect is produced.

The increased vascularity of the periphery of the limb following this operation is seen by the increased volume of the plantar, dorsalis pedis, and popliteal pulses, and the line of demarcation which rapidly forms at the advancing edge of the moist gangrenous patch. This vascularisation of the part should go far in making possible more conservative treatment in the form of low amputations. Low amputations would seem to be preferable to non-operative measures, such as allowing the part slowly to slough off—because of the increased strain thrown upon the subject by the suppuration (lowering both the local and general resistance to the disease). Larger doses of insulin will be required to keep him sugar-free, and they may fail to control the sugar output altogether. Also from economic reasons the time factor is, in some cases, a not inconsiderable one, and convalescence is very much shortened by amputation.

Conclusion.

The method adopted in the treatment of diabetic gangrene as illustrated by two cases was briefly as follows: 1. A very short preliminary course of insulin with radiant heat was given, in order to render the patient more fit for the operation to follow. This was followed by (2) early operation. The operation of choice was a combined method of peri-arterial sympathectomy of the femoral artery in Hunter's canal, with ligature of the femoral vein. This was thought to be preferable to either operation by itself, as the amount of hyperæmia produced, on which the success of the operation depends, was correspondingly greater. (3) After an interval of ten days or a fortnight, low amputation (a Syme's) was performed in the second case as a time-saving measure to ensure more rapid convalescence.

Clinical and Laboratory Notes.

A NOTE ON THE CHARACTER OF THE CEREBRAL CEREBRO-SPINAL FLUID IN A CASE OF GENERAL PARALYSIS.

BY HILDRED CARLILL, M.D. CAMB.,
PHYSICIAN TO WEST END HOSPITAL FOR NERVOUS DISEASES;
AND
W. E. CARNEGIE DICKSON, M.D., B.Sc., F.R.C.P. EDIN.,
PATHOLOGIST TO THE HOSPITAL.

KNOWLEDGE of the character of the cerebro-spinal uid withdrawn by lumbar puncture, in health and sease, is now almost universal. Knowledge of its character when withdrawn by cisternal puncture is fairly common. It is unlikely, however, that many have had an opportunity of examining the fluid in a case of syphilis of the nervous system, in the state in which it lies in the ventricles of the brain, and a recent experience in hospital practice may be of interest.

The patient was infected about the age of 17. He began to develop signs of general paralysis early in 1927, at the age of 41, when he had been elsewhere under treatment for tabes dorsalis, intravenous and oral, for four years. His serum and lumbar cerebro-spinal fluid had given completely positive tests for syphilis in 1923, and gave them again on admission in 1927. Four combined treatments of salvarsan and salvarsanised serum were given; on the three last occasions the serum was run into the right and left cerebral lateral ventricles alternately through a needle passed through a hole drilled in the skull.[1]

* The upper limit of inhibition of hæmolysis was not tested in the first specimen of each. M.H.D. = minimum hæmolytic dose of complement which hæmolyses 1 c.cm. 5 per cent. sensitised sheep's red blood corpuscles.

† Sugar was not tested for quantitatively, a 1 : 10 dilution of Fehling's solution, with an equal amount of cerebro-spinal fluid, giving almost complete reduction, as in most normal cerebro-spinal fluids.

We are not concerned here to defend or otherwise the rationale of treatment by salvarsanised serum. We merely wish to draw attention to the character of the ventricular, as compared with the lumbar, cerebro-spinal fluid; they were withdrawn simultaneously except on the first of the three occasions. From the table of results given above it will be seen that the first specimens of ventricular and lumbar fluid were obtained on different dates. The results suggested that the investigation of fluids obtained simultaneously would be of considerable interest.

A point of interest in connexion with the Wassermann reaction was that, with the ventricular fluids, the hæmolysis tailed off over a considerable number of tubes—there was no free complement in the fluid itself—there being a trace of hæmolysis even in the earlier tubes, whereas with the lumbar fluids the point between inhibition and hæmolysis was sharply defined. Incidentally, in none of the fluids was any blood present, nor were spirochætes detected in any of them.

FATAL CASE OF FOOD POISONING, WITH DELAYED NERVOUS SYMPTOMS.

By A. H. D. SMITH, *M.C.*, M.B., CH.B. EDIN.,
HON. SURGEON AND RADIOLOGIST, LLANELLY GENERAL HOSPITAL.

THE following are notes on a case of poisoning attributable to food.

The patient, a commercial traveller, aged 53, was first seen by Dr. Hugh John, of Llangennech, on July 12th, 1927, about noon. He stated he had always enjoyed good health and gave the following history of his illness.

On July 10th, while out camping with his wife and daughter and three friends, he had a meal about 8 P.M. and ate heartily of a veal and ham pie. All the other members of the party except his wife ate the pie, but his daughter ate only a very small portion. The daughter did no develop symptoms, but all the others, including the wife who did not eat the pie, developed gastro-enteritis. The food eaten by the party on the Sunday, with the exception of the pie, was prepared by the wife.

At 2 A.M. on July 11th one of his friends was taken ill with diarrhœa and vomiting; another had similar symptoms at 8 A.M., and another at 2 P.M. His wife was taken ill on Tuesday; her symptoms seem to have been mainly those of gastritis and she was up and about on Friday. The daughter did not develop symptoms.

The patient left his home by the 9.10 train on the morning of July 11th seemingly quite fit. He arrived at his destination at 10 P.M. and then complained of feeling unwell. His symptoms seem to have been at that time those of malaise, and he went to bed. In the early hours of the next morning he developed severe diarrhœa and vomiting and was seen by Dr. John about noon. At this time he complained of severe diarrhœa and vomiting and of thirst, and gave the history already recorded. On physical examination nothing untoward was found. The pulse was full and regular and the rate was under 100, the temperature was 102° F. The motions were extremely frequent, greyish in colour, and watery in consistence, They contained no blood or slime. Vomiting and retching was very marked, and the vomit consisted of what he had just taken. Dr. John gave him a gr. ¼ pil. morph. and advised abstinence from all food, recommending the patient to take sips of water. The symptoms up to this time were those of a severe gastro-enteritis.

The next day, July 13th, the gastro-enteritis was still very marked but the temperature had fallen to normal. On that night Dr. John asked me to see the case. At that time the patient complained of abdominal discomfort and of exhaustion and thirst. The vomiting and retching were still very severe and the movements of the bowel almost continuous. The temperature was normal and the pulse-rate about 90. The pulse was regular in rate and rhythm and surprisingly good for a patient who had had such severe symptoms and persistent dehydration. He was alert mentally and answered questions readily and clearly and at this time there was not the slightest suggestion of any involvement of the nervous system. He was unable to retain anything given by mouth so morphia, gr. ⅓, was given hypodermically, and those in charge of him were advised to give him brandy ℥ss. in water every two hours and albumin water.

By the morning of July 14th he had improved somewhat and by Friday, the 15th, he was able to keep his feeds down for a longer time. He still, however, suffered from retching and was unable to retain a mixture of bismuth salicyla The diarrhœa had subsided to a large extent, but he w inclined to get out of bed and his mental state was not alert as it had been previously. There was a suspicion a slight delirium. He had also complained of dimness vision and of transient diplopia and there had been suspicion of slight ptosis. I now saw him again late Friday, and suspected from these nervous symptoms t the infection had been by *Bacillus botulinus*. As, howev the onset of nervous symptoms had been so long delay it was felt that the use of antitoxin was not likely to be any value. A marked feature at this stage was the coldn and clamminess of his limbs in marked contrast to his pu which was full and regular and about 90 in rate.

Early on Saturday morning, July 16th, he had what attendants thought was a convulsion. When seen by doctor he was stuperose and not convulsed. The descripti given, however, by those present was most suggesti I was called to see him in the evening. He was in a d stupor and could not be aroused. He did not recognise His extremities were again extremely cold and clam but the pulse was good, regular in rate and rhythm, a about 100. He was retaining his feeds and the diarrh had much improved. In the early hours of the morning July 17th his respirations became very rapid, and he rapi went downhill and died.

The interesting feature in this case is the delay onset of recognisable nervous symptoms in contra to a fairly rapid onset of classical symptoms of gastr enteritis. It was only after five days that evidence involvement of the nervous system appeared. view of the statement[1] that antitoxin has definite val if injected within a few hours of the ingestion contaminated food, antitoxin was not given. I n wonder whether antitoxin treatment might not ha been advantageous even if given late on in the disea

A further interesting feature in this case was t regular and full pulse contrasting with the clammin and coldness of the limbs so suggestive of collap The illness of his wife, who had not eaten the pie, peculiar.

TWO CASES OF ACUTE HÆMORRHAGIC PANCREATITIS.

BY J. D. DHRUV, M.S. BOMBAY, F.R.C.S. ENG
SURGEON, JAMSETJI JIJIBHOY HOSPITAL, BOMBAY.

THE following cases have interesting features.

CASE 1.—A man, aged 45, complained of dull pain the epigastrium for the previous four days. The severity the pain had forced him to take to his bed on the last t days, and for three days there had been severe constipati On examination there was marked tenderness and rigid in the epigastrium. The tongue was moist and cle the temperature was 101° F., and the pulse-rate 120. influenza was prevalent he was labelled "abdomi influenza." Next day the temperature was 102°, and pulse-rate 110, but the patient said he was feeling bet though he looked anxious. On the seventh day the pu rate rose to 140 and the temperature to 104°. The p became more severe and the patient died.

At autopsy patches of fat necrosis were found in omentum and areas of softening and necrosis in the pancre tissue.

CASE 2.—A stout male, aged 40, for a week had continu dull aching pain in the hollow of the stomach, not relat to taking food, though it was worse between 3 and 5 P. It did not interfere with his sleep and for five days continued to attend to his work. Then he took to his b and when I saw him seven days from the onset he acutely ill and had an anxious look. There was rigidity tenderness in the region of the stomach. On question admitted that he had had a similar attack two years bef which had subsided after a week's treatment in bed. Si then he had suffered off and on from flatulent dyspep A tentative diagnosis of perforated gastric ulcer or ac cholecystitis was made. The patient's friends refused allow abdominal exploration, and he was kept under obse tion. He was placed in Fowler's position, and the diet restricted to small sips of water. An enema was gi without result. The tongue was clean and moist.

On the third day after admission he became wor the temperature was 102° F and the pulse-rate 120. the evening, however, the bowels were opened spontaneou he felt better; the temperature fell to 98·5° and the pu

[1] Price's Text-book of the Practice of Medicine, p. 375.

te to 98. But during the same night his condition again ok a sudden turn for the worse; the temperature shot up 104°, the pulse-rate was 140, and localised tenderness was tected in the right iliac fossa.

On the fourth day, in the morning, he became steadily ore ill. He developed severe hiccup and vomited four nes, the vomit being dark-coloured fluid, which was found be bile. Consent was now obtained for operation, and a ght paramedian incision about 5 in. long was made. The ritoneal cavity was opened and the omentum presented elf showing some yellowish areas of fat necrosis. A little ood-stained fluid was mopped out. The stomach and uodenum showed no perforation; a quantity of blood-ained fluid escaped from the lesser sac and the pancreas owed hæmorrhages and presented areas of sclerosis ggesting existence of a chronic pancreatitis. The appendix as adherent to the cæcum. The gall-bladder was distended d some concretions were felt at its neck. After pro-ting the general peritoneal cavity I aspirated a quantity fluid from the gall-bladder. It was black, like Indian ink, d had the same character as what had been vomited in the morning. After incision of its capsule the pancreas was drained through the lesser sac. The gall-bladder was rapidly drained through another incision on the right side. The patient collapsed, however, two hours after the operation and died, in spite of intravenous injection of saline and of pituitrin.

The onset in this case was very insidious; the patient suffered from a subacute type of pancreatitis. It is difficult to explain the lull in the symptoms during the afternoon before the day of operation. Probably the fluid exudate in the lesser sac escaped into the general peritoneal cavity through the foramen of Winslow and led to toxic absorption, giving rise to rapid pulse, high temperature, and hiccup. The vomiting of pure bile was a very striking phenomenon due to regurgitation through the duodenum. I examined the patient specially for cyanosis and for ecchymosis in the loins, which is considered patho-gnomonic by some surgeons, but they were absent.

Medical Societies.

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.

JOINT MEETING WITH THE SECTION OF MENTAL DISEASES OF THE BRITISH MEDICAL ASSOCIATION.

AT a joint meeting held on Friday, July 22nd, in te Edinburgh University New Buildings, Dr. AMILTON MARR (Commissioner of Control for otland) presided and Prof. G. M. ROBERTSON ened a discussion on the

REPORT OF THE LUNACY COMMISSION.

e Lunacy Laws of England and Scotland were, he d, in urgent need of amendment. Great changes social life and in the scientific world had occurred ce the passing of the Scottish Act in 1857, but this t had the advantage that it recognised the amount position of the medical profession in the atment of mental diseases. Under it no layman s called upon to see the patient on certification, l no lay committee was responsible for his removal discharge. To this feature must be ascribed the cess of the Scottish system, which had gained the nplete confidence of the people. No case of proper detention had ever been recorded in the urts. The English Act of 1890 was a complete, ical, and accurately drafted instrument. Its very fection from the legal and administrative points of w had been a calamity to the patient. The medical ect of the problem had been overshadowed by the nting fear of improper detention, so that laws cted for the welfare of the insane person had turned o be to his detriment. One gratifying and mediate result of the Royal Commission had been allay all anxiety in the minds of reasonable people to improper detention; such cases had not been nd. Future legislation, therefore, should not be minated by suspicion and misgivings. The Com-sion had also found that, since the stigma of tification was keenly felt, it should be a last resort l not a preliminary to treatment. The facilities for atment without it therefore called for extensive elopment. The keynote of the past had been ention; the keynote of the future should be preven-n and treatment. The arrangements suggested for untary treatment were satisfactory. For the oluntary three procedures were recommended: Emergency Order, the Provisional Treatment er, and the Reception Order. The first of these, ned by one doctor and a friend or public official, not a certificate of insanity and remained in force seven days only. It appeared quite satisfactory.

The Provisional Treatment Order.

n the provisional order one doctor would make the mmendation, which would last from one to six ths only. It was intended to ensure treatment for the probably recoverable patient without certification. The signature of one doctor only was, however, a mistake; as a safeguard and a second witness or observer only, apart from his value as a second medical opinion, the second doctor must meet with general approval. A niggardly economy where the liberty of the subject was concerned was indefensible, but it was particularly objectionable if the omission of the second doctor were responsible for the repeated visits by laymen.

Another difficulty was the basis of the order, which was made a matter of prognosis, notoriously the most difficult and uncertain problem in psychiatry. It had to be solved by the general practitioner who had little experience and by the justice who had none. Every successful doctor was an optimist, and it might safely be assumed that if this became law every patient, save a chronic or absolutely hopeless case, would get the benefit of the doubt and be treated under the provisional order—an excellent thing. The terms were better expressed in the Scottish Schedule G, which used the words "where the malady is not confirmed" and "with a view to his recovery." The intention could always be honestly remedial, however faintly hopeful the outlook. It would be better to drop the dubious procedure of prognostication alto-gether, and give every patient for whom there was the least hope the benefit of the provisional order treatment for six months. No objection to full certification could be taken after the six months' test had failed, or for chronic cases.

It was a matter of profound regret that the justice had to intervene in the provisional order; such a recommendation was astonishing in a report that recorded no case of improper detention and that breathed medical aspirations and professed thera-peutic and preventive ideals. It was clear that unmedical legal procedures had in the past been the chief impediment to early treatment. The treatment to be given under this order was only temporary and essentially remedial. There was no need for the justice, particularly if two medical men were involved. Miscarriages of justice had occurred in the law courts, yet no comparable cases could be found in the mental hospitals. In Scotland for 70 years thousands of persons had been placed in mental hospitals without seeing a magistrate, and no case of improper detention had ever been found. This record of the medical profession was beyond all praise, and proved that their honour and vigilance were no mean safeguard.

Another safeguard which the Royal Commission did not seem to have appreciated was the Scottish right of appeal to two independent medical men. The sheriff's reception order was wholly given on the written opinions of the two doctors first called in, and the patient, his friends, the sheriff, or the General Board of Control could call in two other doctors, who formed for the time being the supreme and final court of appeal. Thus in Scotland there was a purely medical system that afforded complete protection, had stood the test of time, and satisfied public opinion.

Judicial Intervention.

Infringement of the liberty of the subject without the intervention of the judicial authority was not without precedent in the domain of mental disease. It appeared to have been practised in England for 45 years without abuse, and was still practised in Ireland. Judicial intervention was not desired by the patient nor by his relatives. It was quite alien to medical feeling. It created difficulties, added complications, and caused delay at a time of great trouble. If there must be some form of judicial intervention the Scottish procedure at least preserved the integrity of the medical ideal, respected the sanctity of the home, and introduced the judicial element in a purely legal capacity. The sheriff who examined the certificates was an experienced barrister and a salaried judge; he made no quasi-medical examination of the patient, and if the forms were in order and the facts satisfied him he invariably signed the order. All these duties were just as carefully performed by the General Board of Control, and there was no reason why the certificate should not be signed by that body instead of by the sheriff.

Dr. Robertson then drew a vivid picture of the process of treating a mental patient under the proposed scheme when the justice had to see the patient in his own home, confer with relatives and doctors, and exercise a "directed discretion." Six months later the justice must see him again, and at this time the patient could employ a solicitor; with a manic patient lively scenes might well occur. The more nearly judicial intervention was judicial in character, the more closely would this picture accord with actual events. The perfunctory way in which the justice often performed his duties in the past might have been a saving grace. It was clear that adequate protection existed and was afforded by other means. To Scotsmen this form of amateur medicine seemed a monstrous and intolerable invasion of the sphere of the physician, and nothing less than a caricature and a mockery of medical science and practice. Medical men in England had acquiesced in it in the hope that it would relieve them of some responsibility; that hope had not been fulfilled.

In conclusion Dr. Robertson said that the provisional treatment order formed the most striking departure from precedent of all the recommendations in the Report of the Royal Commission. It conferred its privilege not only on voluntary patients, but also on volitional but resistant ones. For the enjoyment of its full benefits, however, there should be certain modifications. Two doctors should be called in, with the right of appeal to two independent doctors. This would make it unnecessary for the judicial authority to visit and see the patient, a requisite which perpetuated those legal formalities that had in the past delayed treatment, blighted attempts at prevention, and differentiated mental disorders from other illnesses. The justice should be replaced by the Board of Control, a strong medico-legal body accustomed to visit patients and familiar with the requirements of the law. The conditions of the order should be altered, from prognosis to the terms of Schedule G.

Discussion.

Dr. E. MAPOTHER said he had been profoundly disappointed with the Report, which was chiefly devoted to the doubtful prevention of non-existent abuses. The public were much more concerned with the questions of where and how than with the precise procedure under which they were to be treated. Voluntary treatment in county mental hospitals, for instance, would make a lot of difference. The Report lacked constructive imagination. The distinction between voluntary cases and involuntary was, *pace* Prof. Robertson, not clear-cut, and this ignoring of the voluntary patient was the Report's chief defect. Many of the most recoverable cases were voluntary, and those ought to have the best treatment without the intervention of justices. Again, under the Report, the voluntary patient who passed into a state of unwillingness would have to be certified within a month (the Provisional Order was nothing but certificate, except that the patient saw a magistra more often). Some other method was necessary fe these patients, by which they could be treate temporarily outside an asylum. Another grav objection was that the doctor might have to wait seve days to have his patient seen by a magistrate, ar that would drive most mental consultants to th use of the emergency order. He was in favour having a special certifying medical man to gi certificates under the Provisional Order. Finally h pointed out that, when the Provisional Order te minated and a reception order was in preparatio a justice, assisted by his clerk, examined the doct and the patient. The patient might choose anyone h liked to attend on him, and the justice could call upo the doctor to "justify" his certificate. This kind trial, at which the patient could be represented b counsel and the medical man could not, was mo objectionable.

Dr. T. B. HYSLOP reminded the meeting that th first duty of a practitioner was to his patient, the ne to the community, and the last to himself. The fear certification and the stigma which it attached to th family of the patient were, he said, often mo formidable than the disease and capable themselves contributing to the development of mental disorde He desired a sporting chance of relieving patients their difficulties without imposing this stigma upo them, and for this reason he welcomed the Repo which would remove many of the evils of certificatio He favoured the elimination of the judicial authorit the selection of magistrates with knowledge of th subject, and the provision by local authorities specialists to advise the general practitioner.

Dr. W. F. MENZIES stated that medical men h everyone on their side in this matter—practitione patients, relatives, and friends; against them we only the lawyers and the cranks. Lawyers, howev were necessary to the community. He sympathis with the medical man who, under the Provisiona Order, had to have three interviews with a justice a his clerk, and perhaps to forego a whole day's work a travel a long distance to settle whether his patie was to be immured or not. The profession had decide firmly whether to oppose the Royal Comm sion's Report altogether, or to take the good points it and concentrate on amendment, keeping in t forefront the needs of the non-volitional case. He w against opposing the Report, but held that th attendance of justices at the patient's home w absolutely impossible in any but the largest centr It usually took a justice three weeks to see a patient t present, and with 100 voluntary patients out of 200 a hospital the scheme would break down. Thr quarters of the non-volition patients would have to e discharged because no justice would ever see the He suggested that the visiting committees and boa of management of county mental hospitals should e made justices ad hoc.

Dr. RISIEN RUSSELL said he would be content f only England had the privileges of Scotland. e wanted to be allowed to treat patients effectively r at least a year without legal intervention. The iss were: should the profession have the whole say n the matter of certification? and should a doctor e immune from civil action for wrongful certificatio? Treatment was a medical matter, but depriving a per n of civil rights was a legal one. The profession co d only claim protection if they accepted legal interv tion and were prepared to give evidence on oa. The examination of the patient by a legal authori y need carry with it no publicity, and it would be n advantage if the justice had no medical training, r he would view the matter from a standpoint differ t from the medical one. He welcomed the Provisio al Order; the emergency order had been so much abu d in England that there was every justification for e interposition of a magistrate. It was reasona le to have a specialist also signing the certific e, and to accept every safeguard of the patie 's interests.

Dr. DONALD ROSS (Cassel Hospital) quoted the mark of a medical superintendent at Zürich that he borderline between the sane and the insane was rtification alone, and advocated that one of the gnatories should be a member of a hospital staff.

Earl RUSSELL said that the Royal Commission had een much impressed by Dr. Robertson's evidence and ie system he was able to administer. They did not ndervalue the medical point of view, but when dealing ith legislation it was no use discussing a matter from iat aspect. The public feeling must not be over-ooked, and an anti-medical view had been presented) the Commission. For some reason or other there as in England, among the great mass of the popula-on, a suspicion of doctors, and no legislation that nored that could hope to get through Parliament. he House of Commons represented the stupidity as ell as the intelligence of the people. Those opposed) the medical view were not, as Dr. Menzies had iggested, only lawyers and cranks. A vast body of ninformed and uneducated public opinion regarded ie doctors as only too ready to certify and without ason. No doubt we should get on as well without ie judicial authority; indeed, the Board of Control as the real safeguard. It was entirely undesirable r the justice to have medical knowledge; it was not r him to form an opinion, from a very imperfect edical diagnosis of his own, whether the patient were ne or not. His duty was to see that care had been ken and that the papers were in order. There were ie gravest objections to anything like a public or ivate trial; the less the proceedings took the form a forensic contest the better. To treat voluntary atients involuntarily would destroy the whole dvantage of the voluntary system. The urgency order as often used unnecessarily and it was important that should not be abused.

Sir DAVID DRUMMOND (Newcastle-on-Tyne) ex-essed agreement with Earl Russell and pleasure at ie good reception the Association had accorded to ie Report. He regretted that it had not been ossible to protect the practitioner more thoroughly.

Sir FREDERICK WILLIS (Chairman, Board of Control) id that the Minister of Health was very anxious to ass a new Lunacy Law, but the Ministry was not arliament. Parliament was governed by public inion, which was still "frightfully superstitious." mething more than formalities prevented people tting mental treatment; they hated to admit that ere was anything mentally wrong with them because sanity was still regarded as such a dreadful thing. atients would be better divided into three groups—luntary, involuntary, and unwilling. It was not an fringement of a patient's liberty to give him treat-ent. It was a pity that the Commission's Report pped short at the statement about treatment for ute recoverable cases; it should have gone further d stated what the Commissioners thought right. was not for them to consider public opinion. The ard of Control believed that adequate safeguards uld be obtained without the intervention of the stice, and suggested that the "Provisional Order" tients should only be admitted to institutions which e Board had previously approved. The Board had en much distressed by certain recent legal cases. appeared that a jury was an absolutely unsuitable bunal for this purpose. It was quite absurd for such body to say they were satisfied that an individual d been sane 12 years before. There was no ground insisting on two certificates other than the grati-ation of public sentiment, and a financial point s involved. It was extremely important that eryone should do what they could to break down e superstition surrounding mental illness.

Sir ARTHUR ROSE (Scottish Board of Control) said at the Report was a very valuable strategical con-bution, and had secured unanimity by going only st as far as would be accepted. A minority report uld have been most harmful to legislation.

Dr. C. O. HAWTHORNE (London) said that the public titude towards certification must be most carefully nsidered. The Board of Control was not to blame; it came on the scene too late. The stigma remained even if certification were found to have been wrong a few hours later. Enormous importance was attached to the liberty of the subject. But in addition to these two very important factors there was a third which had impressed him, and that was the position of the doctors at this moment. The practical situation was that many doctors were not only reluctant but determined not to sign certificates under the present circumstances. Deeds of partnership were being drawn up with the condition that neither member should undertake this work. Here was another sentiment which must be respected. Doctors alone were competent to judge when mental disorder existed and how it should be dealt with. Another sound position was that the State came in and said: This is a form of medical treatment which invades the liberty of the subject, and such treatment shall not be imposed until we are satisfied that it is necessary. That being so, it was for the State to accept responsibility when it assumed authority. The doctor might be asked for advice—i.e., for his contribution in the form of evidence, and ought to have the same immunity as other witnesses. The choice of action lay between the high academic doctrine that the public must be educated, and the practical step of accepting the State's claim to intervene, but emphatically telling it that it must then accept responsibility.

Dr. C. H. BOND (Commissioner, Board of Control) confirmed Sir Frederick Willis's account of the attitude of the Board of Control. He related the history of the Committee of Inquiry into the Lunacy Acts in 1884, when the Earl of Shaftesbury was chairman of the Lunacy Commission, and vividly described the distress of the great-hearted Earl, particularly at the suggestion of judicial intervention. Dr. Bond asked whether it were yet too late to relieve the justice of a task for which in most instances he had no taste. If the public really knew this piece of history and the complete absence of cases of wrongful detention, they themselves would give the pendulum a swing in the other direction. He did not think the law should impose on the Board of Control the duty of visiting cases in single care; any visitation should be done by medical members.

Dr. L. V. BRIGGS (Boston, Mass.) described his experiences on the Board of Control in Massachusetts under three different political administrations. The medical societies there had succeeded in educating public opinion by joint meetings and discussions and by belittling the ideas of heredity in mental disease and of the stigma of entering a mental hospital. A review of 28,000 certified cases had shown an hereditary factor in 54 per cent. only. In his State there was a system of six months' parole on release from hospital; during that time the patient could be brought back to the hospital without legal proceedings. The magistrate had a right to see the patient, but exercised it in less than 10 per cent. of cases. In only one instance had damages been awarded against a doctor, and then the judge had intervened, saying that it was against the evidence and against the law.

DONATIONS AND BEQUESTS.—Mr. Henry Peter Hodge, Kettering, left £250 to the Kettering General Hospital and £50 to the Kettering District Nursing Association.—Among other bequests the late Mr. George Edwin Lowe, J.P., of Sutton Coldfield, Warwickshire, left £2000 each to the Princess Alice Orphanage, New Oscott (a branch of the National Children's Home and Orphanage), the Birmingham General Hospital, the Queen's Hospital, Birmingham, and the Devonshire Hospital, Buxton; £1000 each to the Home for Incurables, Leamington, the Women's Hospital, Birmingham, and the Children's Hospital, Birmingham.—The late Mrs. Sarah Wood, of Blackheath, left by will £1000 to the Victoria Cottage Hospital, Maryport, to found a bed; £100 each to St. John's Hospital, Blackheath, the Blackheath and Charlton Cottage Hospital, and the Miller Hospital, Greenwich.—The late Mr. Edmund Thomas Child, of the Temple and Wimbledon, S.W., among other donations, left £1000 each to St. Andrew's Hospital, Dollis Hill, and the Hospital of St. John and St. Elizabeth, Grove End-road; £100 each to North Wimbledon Hospital, the South Wimbledon Hospital, and the Central Home for the Poor Mentally Defective Children, Worcester.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT EDINBURGH.

(*Continued from p. 235.*)

SECTION OF MEDICINE.

WEDNESDAY, JULY 20TH.

Prof. G. LOVELL GULLAND (Edinburgh) presided at the first session of this Section when Prof. H. MACLEAN (London) opened a discussion on the

RESULTS OF INSULIN THERAPY IN DIABETES MELLITUS.

The four years which had elapsed since insulin was introduced were sufficient, he said, to show its influence on the disease. Insulin, which was essential for the correct use of sugar and fat, could be supplied in adequate amounts, and the chief difficulty in treatment arose in balancing the diet and the insulin. Much had been learnt in the past about the value of dietetic restrictions in the treatment of diabetes but the results had been disappointing. Although the patient lost all symptoms of the disease and did well to begin with, after two to four years a deterioration took place and death usually occurred as a result of coma or some intercurrent disease. The so-called diabetes in elderly subjects often presented a different picture from that occurring in young people, as glycosuria was the only symptom and ketosis rarely occurred. He did not think that this condition was true diabetes but a simple glycosuria, dependent on an inability to store sugar in the normal manner in the liver and muscles. Such glycosuria often did no harm though the condition sometimes developed into a true diabetes. Dietetic treatment worked admirably with this type of patient, whereas without insulin the true diabetic rarely lived more than four to six years.

Since insulin had been used, 291 patients had been treated in the Medical Unit at St. Thomas's Hospital. All these showed a definite ketosis and the majority were young or middle aged. Cases with ordinary glycosuria without ketosis were not included. Every patient had been first treated as an in-patient and afterwards watched in the out-patient department.

Year.	Admitted.	Deaths to date.
1923–24	77	5
1924–25	76	2
1925–26	68	3
1926–27	70	2
Total	291	12

Several of these patients were admitted in coma; a number developed coma, three of them on two occasions; all these were now doing well. Two patients with tubercle bacilli in the sputum were still alive and in fairly good health. Of the 12 deaths, one girl of 19 developed coma outside and was treated by her own doctor; another was admitted at a late stage; three recovered from coma but died of heart failure. In all the others coma developed as the result of some such complication as influenza, pneumonia, or a septic lesion. The death-rate was nearly 4 per cent., which was an extraordinary improvement over the results of dietetic treatment. It was probable that of the 77 patients admitted in 1923–24 no less than 38 would have died; whereas, with insulin 72 were alive and well. Only one patient had been seen who did not respond to insulin, and as an autopsy was not allowed it was not possible to say that no other complication was present. These figures showed that the disease had been shorn of many of its terrors and it ought to be possible to control any uncomplicated diabetes and to restore the patient to a fair degree of comfort.

There were, however, Prof. MacLean admitted, some difficulties in the treatment. An acute illness caused the insulin to lose its effect and the dose must be considerably increased. Very often the medical man took the view that some complication which made the patient unable to take the usual die indicated a decrease in the dose of insulin. Suc treatment was often fatal as the dose of insuli should be increased at an early stage of the com plication. If this was done the grave consequence could often be avoided. The results with childre were, on the whole, good, as 30 children under th age of 10 had been treated in four years and the were all alive and in good health. The hopes of a re cure occurring in children had not been fulfilled a the insulin could not be abandoned although it ha been reduced in some cases. Elderly persons responde to insulin equally well and symptoms such as weakne or neuritis improved. Insulin was of the utmo service when an operation was necessary; wit insulin a diabetic had about as good a chance und the knife as a normal person. The mortalit statistics were not so good as would have bee expected as there had been no diminution in th number of deaths due to diabetes. This might b due to the fact that the incidence of diabetes ha largely increased and that without insulin the deat would be much greater. The examination of th tables showed that the age-incidence had shifted ar that the majority of deaths occurred in elderly person These had probably died from another disease.

The results with comatose patients were ver striking, but much depended on the quickness ar energy of the medical attendant. If treated ear recovery should be the rule, especially if the patie was young and otherwise healthy. The use of alka in coma was contra-indicated, as Goldblatt ha shown that a dose of alkali prolonged the state ketosis produced in a healthy adult by carbohydra starvation. Although it was better to aim at keepi the urine sugar-free and the blood-sugar norm many patients did very well even though glycosur existed. He deprecated giving insulin more tha twice a day because of the effect on the mentali of the patient. Once the patient knew how estimate his diet it was unnecessary to weigh eve meal. None of the pancreatic mouth preparatio on the market had, he said, the slightest effect on t disease. Synthalin, the newest synthetic produc did produce some effect in certain cases, and it w conceivable that some effective synthetic preparati would be discovered. Meanwhile, the view must accepted that insulin was the only useful substan in the treatment of diabetes.

Prof. PETRÉN (Lund, Sweden) said it was t early for him to draw general conclusions as t total number of cases was too small. He ha however, analysed the figures for patients admitt in coma.

Admitted in coma	57
Recovered	42
Died in hospital	4
Died in coma at home	4
Died at home of other diseases	7

These figures were very satisfactory and were ve similar to those of Joslin. He thought that intravenous injection of dextrose at the outset treatment was bad practice. The diet which he us subsequently was one low in protein and the carb hydrate in which did not exceed 50 g. He had be struck by the mortality figures for Holland; bel the age of 50 there was a decrease in the number deaths, from 50 to 65 there was no change, above there was an increase.

Dr. R. D. LAWRENCE (London) said that t properly treated diabetic patient was so well that one would know he had diabetes unless he was se taking his food or an injection. Failure was due the following causes: 1. The presence of anoth disease; he had seen three patients with carcinom of the pancreas. 2. Coma—of the comatose patien six had died out of 24; these deaths he ascribed circulatory failure and he gave small doses of adrena to aid the heart. 3. Resistance—he had only se one person who was insulin-resistant; he requi 400 units a day to keep the urine sugar-free. All t pancreatic extracts on the market were useless.

isagreed with Prof. MacLean as he considered that o real distinction could be made between the iabetes occurring in old people and that in young dults. The difference was only one of degree; the ondition in elderly people should be treated efficiently.

Dr. P. J. CAMMIDGE (London) divided cases into ree groups: (1) those with defective utilisation and efective storage; (2) those with defective storage nly; and (3) those with a low renal threshold but o other defect. The mortality in the first group had een decreased from 49 to 20 per cent. by the use insulin; in the second group from 9 to 4 per cent., hile there were no deaths in the third group. Death as always due to another disease. He had used a y preparation in a few cases along with insulin nd thought that it had helped a little.

Dr. O. LEYTON (London) had only known two sulin-resistant patients. One was still alive and irly well, but the other had died in coma in spite large doses of insulin and no septic disease had en found at the autopsy. In only one case had a ue recovery taken place. He thought that the ood-sugar should always be kept below 0·15 per nt. He had analysed 325 cases; of these, 6 per nt. had died; 27 had increased the dose of insulin; had kept the insulin the same; 26 had decreased e insulin; 2 had given up insulin; 33 had increased e diet; and 5 per cent. had decreased the diet.

Prof. D. MURRAY LYON (Edinburgh) said he gave sulin to patients for the following reasons: If a vere ketosis persisted, if severe emaciation was esent, if the limit of carbohydrate tolerance was o low to support life in comfort, if the urine con- ined sugar in spite of careful dieting. He thought at if the disease was properly treated it was not ogressive. Recovery took place in one case where e insulin had been decreased from 170 units to nil d the patient had kept well for 15 months. The uses of a fall in tolerance were as follows: (1) omis- n of insulin, (2) carelessness in the diet, (3) emotional sturbance, (4) toxæmia of some kind, (5) lack of e usual exercise. He thought that the urine should ways be kept free from sugar and that three doses insulin should be given if necessary. He dis- reed with Prof. MacLean in the distinction he had awn between the glycosuria of elderly persons and ung adults.

Prof. L. BLUM (Strasbourg) said his early results th coma had not been so good as his recent ones. had now increased the dose of insulin considerably d gave it half-hourly if necessary. The urine was amined at frequent intervals and if sugar was sent another dose was given. When no sugar s present, estimation of the blood-sugar was visable, but changes in the patient's condition were en a guide to the correct dosage when he had come conscious. He disagreed with Prof. MacLean out the toxic action of alkalis, as he had found that e cells of the cerebral cortex of comatose patients ntained much less sodium than those of healthy rsons; alkali should therefore always be given to matose patients.

Dr. G. GRAHAM (London) said that the tables for gland and Wales showed a steady rise in mortality m diabetes since 1900, broken only from 1917–19, en strict rationing caused a decrease, mainly in tients over 50. Since the introduction of insulin re had been a slight decrease in male mortality, t female mortality was actually higher than ever. analysis of age-groups showed a big decrease in decades under 50, undoubtedly due to insulin, in the 50–60 group male deaths had only reased slightly while female had increased, and er 60 both had increased considerably. The rease after 60 was partly due to other diseases, also to the belief that after that age diabetes s a mild condition which required little treatment. believed that the condition was essentially the ne as that in young people but developed more wly. It should be treated drastically as con- erable recovery might take place. As a proof of healthy condition of insulin patients, he instanced two girls who had begun to menstruate normally and four women who had suffered little harm from a pregnancy although this was always an added danger. He did not think alkalis did harm to comatose patients; in this condition if a blood-sugar estimation could not be made he always gave a dose of 50 g. dextrose.

Dr. C. G. LAMBIE (Edinburgh) said that diabetes in elderly people showed certain differences; insulin had a much greater effect on the sugar and little disturbance took place when insulin was stopped. In them the respiratory quotient was normal. He thought that the diffusion of glucose into the cells must be different, especially as the symptoms associated with hypoglycæmia in young adults occurred when the blood-sugar was still high. The difference might be explained by the presence in the elderly person of a substance which countered insulin. These patients should be prevented from passing sugar either by diet or by insulin.

Dr. F. M. SMITH (Harrogate) spoke of psycho-neuroses playing a part in hindering full recovery.

Prof. MACLEAN replied briefly. Elderly persons, he said, should certainly be treated properly whatever views were held as to the condition at their age. Alkalis did no harm to comatose patients in small doses.

THURSDAY, JULY 21ST.

At the second session a discussion on the

TREATMENT OF ACUTE LOBAR PNEUMONIA

was opened by Prof. JOHN HAY (Liverpool). Pneumonia, he said, killed 36,990 persons in England and Wales in 1925, the mortality being approximately 20 per cent. It was admittedly an infection in which the causal organism was the pneumococcus, either alone or in combination with other organisms, the primary site of infection being in the lungs. The outlook depended on the virulence and type of infection and the resistance of the patient.

Type.	Incidence in adults—	Mortality per cent.
1	nearly one-third	25
2	,, one-quarter	33
3	,, one-tenth	50
4	more than one-quarter ..	10

Out of 100 cases 75 would probably survive, 10 to 15 would probably die, leaving 10 to 15 in which correct treatment and good nursing might turn the scale.

As regards prophylaxis, patients nursed in a general ward should be screened off, sputum and clothing disinfected. Every nurse should be taught to hold a sheet of paper or gauze between the patient's face and the doctor's. Gargling with an antiseptic was advisable for those in attendance. Prophylactic injection of large doses of pneumococci had proved useful in the mines of South Africa in diminishing both incidence and mortality. Such protection was certainly advisable in the case of those nursing or treating pneumonia. The presence of anxious relatives made it difficult for the doctor to maintain a cool and balanced judgment; the tendency therefore was to do too much. The common cause of death in uncomplicated pneumonia was cardiac failure, the three important factors in its causation being (1) toxæmia, (2) anoxæmia, (3) stress on the right heart.

The main essentials of effective treatment were fresh air and complete rest. A fire, but no fug. No gamgee jacket but light loose clothing, opening down the front. Every unnecessary movement was to be avoided. Tepid sponging made the patient more comfortable. Plenty of fluid and fluid only should be given during the first 48 hours—water, glucose lemonade, fruit juice, and diluted milk; also tea or coffee, but not late in the day. Later, lightly boiled eggs and biscuits but not soups. At the onset calomel or salines should be given, and if necessary a simple enema. Distension of the abdomen should be watched for; it might be a grave complication by hampering the action of the diaphragm. If it occurred milk should be stopped, an enema given or a rectal tube inserted, and if necessary pituitrin injected.

About specific treatment there was considerable difference of opinion. His personal attitude toward the therapeutic value of vaccines in pneumonia was frankly critical. All the advocates of it stressed the importance of vaccination within the first three days. Captain Malone's paper, published in 1925, seemed to justify the conclusion that early vaccination proved effective in lessening the duration of the fever and accelerating the crisis. Type 1 serum appeared to be useful in Type 1 pneumonia if injected intravenously in doses of 100 c.cm. every eight hours.

Meanwhile symptoms were to be treated. Pain was incompatible with rest and must be mitigated. Strapping might be all that was required, or a mustard poultice or ice-bag might be effective. So long as the air passages were dry, morphine or other opiate, such as Dover's powder or omnopon, might be given. Insomnia was to be combated early with an ounce of whisky or brandy or paraldehyde ʒii. After the fifth day opium should be given very cautiously, especially if there was much secretion in the bronchi. From the first the measures should be directed towards the prevention and treatment of cardiac failure. Vasomotor tone was to be maintained by hydrotherapy. The depth of respiration could be increased by cool fresh air and the relief of pain. Toxæmia was met by specific treatment and by attention to the intake of fluids and elimination by bowel and kidneys. Oxygen was to be administered at the first indication of cyanosis; it was probably the best cardiac stimulant. The funnel method was futile. More efficient was the nasal catheter, the opposite nostril being blocked with cotton-wool; better still was the mask, but patients would rarely tolerate anything applied over nose and mouth. Barach had described a glass nose-piece and an oxygen tent. Digitalis had been shown to have a favourable action on the contractile power of the heart, quite apart from controlling its rate. Its routine use was of value, 45 to 60 ♏ of tincture being given from the start. If fibrillation occurred and if no member of the digitalis group had already been given, there should be no hesitation in injecting strophanthin intravenously.

No scientific evidence had been advanced in favour of the view that alcohol was a direct cardiac stimulant. In a series of 150 cases the mortality of those treated with alcohol was 15 per cent. greater than in those in which alcohol was not used. He was convinced, Prof. Hay said, that the prognosis in any particular patient was rendered graver by repeated doses of alcohol administered to prevent or to counteract cardiac failure. Alcohol was only of use to pneumonic patients under certain well-defined conditions, such as sleeplessness. Alcohol had indeed been shown to inhibit the immunising process upon which recovery depended. Glucose might be given by mouth or intravenously. Pituitrin was indicated if the blood pressure fell. Caffeine was a direct cardiac stimulant. Strychnine was very widely employed but its reputation exceeded its merits. Engorged jugulars, an increase of cardiac dullness to the right, and marked cyanosis justified venesection, but the relief afforded was only temporary. In practice the wise physician used few drugs.

Prof. W. H. WYNN (Birmingham) described some remarkable results of treatment with vaccines. These were best made of fresh cultures of virulent organisms. The first dose for an adult should be at least 100 million. Failing fresh cultures a stock vaccine could be used. If injected in the first 24 hours the patient's temperature dropped and general improvement occurred. The earlier the injection the more sure was the result. He showed lantern slides illustrating the almost uniform fall in temperature and in mortality-rate as a result of vaccine treatment.

Dr. H. MORLEY FLETCHER (London) emphasised the importance of keeping the patient quiet without repeated examinations. He advised giving digitalis, preferably as the tincture, as soon as the diagnosis was made. He quoted Dr. Armstrong's work for the Medical Research Council on the action of sodium nucleinate in pneumonia, in which no evidence was obtained that the immunity reaction was influenced by such injections. Dr. Fletcher had made clinical observations not only in lobar pneumonia but also in other acute infections with a low or moderate leucocyte count. The results were practically negative both as regards leucocytosis or benefit to the patient. Oxygen was of great utility but must be given early, systematically, and in sufficient quantity, when it calmed delirium and promoted sleep. The most useful method was the nasal tube.

Prof. R. J. S. MCDOWALL (London) spoke of the relief of high venous pressure by bleeding. He was of the opinion that when alcohol did have any good effect it was by lowering the venous pressure. Shallow respiration was the chief cause of anoxæmia.

Dr. L. S. P. DAVIDSON (Edinburgh) said he was convinced of the value of serum treatment and of prophylactic injections. A bad outlook must be expected if the sputum gave a pure culture of pneumococci. The worst cases gave a positive blood culture late in the disease.

Sir JAMES BARR (Liverpool) spoke of the importance of the heart in prognosis.

Dr. A. F. HEWAT (Edinburgh) regarded alcohol as essential in the treatment of all cases. The value of oxygen was also undoubted.

Dr. F. M. GARDNER-MEDWIN (St. Asaph) said that if sodium bicarbonate and glucose lemonade were given along with sodium nucleinate a crisis was initiated within 48 hours in nearly all cases.

Dr. D. H. BALLON (Montreal) showed an instructive series of X rays of the chest before and after lipiodol illustrating its aid in the diagnosis of cavities and in the classification of types of bronchiectasis.

FRIDAY, JULY 22ND.

Dr. R. A. FLEMING (Edinburgh) took the chair at the third session, when a discussion on the

PATHOLOGY AND TREATMENT OF PERNICIOUS ANÆMIA

was opened by the President, Prof. G. LOVELL GULLAND. The clinical picture of the disease, he said, was well established; its variations depended on the acuteness and severity of the attack and on the part of the body affected. A blood count was necessary for diagnosis; the principal criteria were a high colour-index, the presence of megalocytes (with or without megaloblasts), and a leucopenia. The platelets were reduced in number but increased in size. The high colour-index was due to the production in the bone-marrow of megaloblasts instead of normoblasts as the result of a toxæmia which affected the blood and marrow. This toxæmia was prone to occur in certain classes of people, more especially those of middle age and those who had a hereditary weakness of the bone-marrow. The toxin was still unknown, but certain facts about it were established. The it was slow in its action, and gradually cumulative until its maximal effect was produced. The patient as a rule recovered from the first attack either because the toxin was exhausted or because a relative immunity was produced. The process was repeated one or more times. The toxin was regarded as hæmolytic but it was probable that both the circulating red cells and those in the bone-marrow were poisoned and rendered a more ready prey to the ordinary phagocytic processes occurring in the bone-marrow, spleen, hæmolymph glands, liver, and elsewhere. The neutrophil series of leucocytes were also affected; these often did not exceed 4000 per c.mm. even when a septic condition was present. Other changes due to the toxin were sclerosis of the cord, necrotic areas in the liver, together with punctate basophilia of the red cells.

The organism which produced the toxin was not known as the blood culture was always sterile and no organism was seen in a stained blood film. A hæmolytic streptococcus had been suspected, but the changes in the bone-marrow were quite unlike those occurring with the known streptococcal infections. The same argument applied with still greater force to the col-

bacillus. Recent experiments by Moench, Kahn, and Torrey had suggested that the presence of *B. welchii* in the intestinal contents caused the condition. The stools of 33 patients contained more of this organism than those of the controls, but the bacilli were not more potent in causing hæmolysis than those of the controls. If *B. welchii* was in fact the cause the wall of the intestine must be more permeable than usual. Kahn and Torrey had damaged the wall of the stomach of monkeys and after feeding with cultures of *B. welchii* had seen the development of an anæmia similar to pernicious anæmia. This work was suggestive but needed to be confirmed. The evidence in favour of a spirochæte or protozoon was not good. It had been suggested that the hæmolysis was due to deficiency in cholesterol in the blood. Cholesterol when present in normal amounts presumably kept the hæmolytic unsaturated fatty acids in check; if the cholesterol was reduced in amount, hæmolysis might occur. The cause of the decrease in cholesterol was quite unknown. A more important point was the achylia, which was practically constant. Pernicious anæmia had developed in patients who had had achylia for many years and achylia was often present in the relatives of patients with pernicious anæmia. On the other hand, achylia frequently occurred in normal people and in many debilitating conditions. Achylia would cause a change in the intestinal flora, but to establish a causal relation the change in the flora should be present before the pernicious anæmia developed, for otherwise the changes in the flora might be due to the anæmia. Although the cause of the cryptogenic or idiopathic pernicious anæmia was not known there were other large groups in which the cause had been established. In bothriocephalus anæmia a cure followed the removal of the worm. The condition in horses was due to infestation of the gastric mucosa with the larvæ of certain flies. It also sometimes occurred in the course of sprue, malaria, syphilis, pregnancy, and over-radiation with X rays. Thus there were many conditions, known and unknown, which could produce megaloblastic anæmia.

Treatment was unsatisfactory from the point of view of ultimate cure, but nearly 100 per cent. recovered from the first attack and the great majority from the second. It was in the later relapses that the real difficulty occurred. Rest, fresh air, cheerful surroundings, general tonic measures were as important as in any other toxic condition. The diet must be regulated by the alimentary condition and varied between a full diet and peptonised milk. Minot and Murphy had used a rich liver diet, but his experience with this was limited; several patients had done well but others had not tolerated the diet. It was very important to regulate the bowels and colon lavage was often of benefit. Hydrochloric acid was used as a routine measure, for in medium doses it helped the appetite, but he had not found that the large doses advocated by Hurst were well tolerated. Arsenic was the standby; it was best given as the hydrochloric acid solution by mouth, the dose being gradually increased until the limit of tolerance was reached, and then maintained until the colour-index fell below unity. Iron should then be substituted. Organic preparations of arsenic had been of little use in his hands. Blood transfusion was not curative but might be of great service in helping a patient round a critical corner when the vitality was exhausted by the toxæmia. Splenectomy was advocated but he had never advised it. So much attention was now being focused on the disease that we might surely hope for advance; for himself he expected it from the side of the chemist or the bacteriologist rather than of the clinician.

Prof. W. K. HUNTER (Glasgow) said that there were two marked groups of pathological change, those in the liver and those in the bone-marrow. The net result was a hæmolysis of the red cells produced in the abnormal bone-marrow. Other points of importance were the family predisposition and the presence of an infection of some sort.

An important paper on the Treatment of Pernicious Anæmia with a Diet Rich in Liver, by Prof. G. R. MINOT (Boston, Mass.), was read by Dr. G. D. MATHEWSON. This diet consisted of 5 to 9 oz. of liver together with some red meat, a small amount of fat, and a reduced carbohydrate ration. In the last three and a half years 125 patients had been thus treated, the blood count rising to 4–4½ millions. The first sign of recovery was a rise in the number of reticulated red cells. These increased from the normal 1 per cent. to 20–30 after six days, remained high for about ten days, and then fell again to normal. The colour-index fell to less than unity, and the yellow colour of the skin and bilirubin in the blood disappeared, the average diameter of the cells becoming normal. Of the 125 patients, 60 had been treated for one year and their average cell count was 4·5 millions; 18 for two years and the average count was 4·6 millions; and three for three years and the average count was 4·8 millions. The achylia persisted in the 20 cases examined. The liver should be eaten either cooked or raw; it should not be boiled for a long time; it could be taken as liver pulp in 5-oz. doses twice a day. There was little difficulty in persuading the patients to continue the diet, as they felt so much better. The exact dose required after recovery was as yet unsettled. Some patients kept well on 5 oz. three times a week. An extract had been prepared which contained nitrogen in a non-protein form. The experiments with this were proceeding and were promising.

Prof. H. VAN DEN BERGH (Utrecht) said that complete absence of hydrochloric acid was most important in the diagnosis, as was poikilocytosis, which he had only found in one healthy patient and in records of two others. He held that the hæmolysis was the basic pathological fact and that the blood destruction took place in the spleen, as no free hæmoglobin was ever found in the plasma. He thought that the real cause was probably a protozoal infection.

Prof. KNUD FABER (Copenhagen) said that he had seen typical pernicious anæmia develop after a stricture of the ileum and with sprue, which had arisen in Denmark as well as abroad. In the idiopathic type achylia was constant and the intestinal flora was changed. He had known the disease to follow gastrectomy, but the fact that achylia was often present in patients who never had any symptoms was difficult to explain. Similarly many patients with bothriocephalus never showed any signs of anæmia. He had seen some patients recover after taking liver, and it would be most interesting to see if the anæmia of bothriocephalus and sprue would also improve.

Dr. A. F. HURST (London) gave figures to show the effect of achylia in causing the incidence of pernicious (Addison's) anæmia. He had known the disease follow achylia due to alcoholic gastritis, also in two cases of cancer. In the latter condition he thought the patients rarely lived long enough for the condition to develop. Dr. F. A. Knott had examined the duodenal contents of 37 cases and had found a hæmolytic streptococcus in 97 per cent., *B. coli* in 94, a staphylococcus in 40, but never any *B. welchii*. The achylia permitted the infection of the small intestine and made the contents more alkaline. He thought that prophylaxis should be practised and septic teeth removed. Acid should be given to persons with achylia, and it was quite easy to get patients to take 1 drachm in 6 oz. of orangeade or lemonade with their meals.

Dr. L. SCHIFF (Cincinnati) gave figures showing the bilirubin content of the blood in secondary and pernicious anæmia.

Dr. STANLEY DAVIDSON urged the claims of *B. welchii* as the cause of the hæmolysis.

Dr. W. E. COOKE (Wigan) showed pictures of the neutrophil cells in which all the young forms had disappeared and only those with multilobular nuclei remained.

Dr. SALISBURY SHARPE (London) thought that a spirochæte was responsible.

Prof. GULLAND expressed his appreciation of a stimulating discussion which had clarified many obscure points.

SECTION OF MEDICAL SOCIOLOGY.

FRIDAY, JULY 22ND.

THIS Section met under the Presidency of Dr. F. KAY MENZIES (London) to discuss the

FUTURE RELATIONSHIP OF MUNICIPALITIES TO THE VOLUNTARY HOSPITALS.

Mr. H. L. EASON (Guy's Hospital) dealt chiefly with the situation in London and said that the solution of the problem must vary with varying local conditions. The fundamental factor was the education of the medical profession; the teaching hospital must have the power to select for admission every type of case. He went on to enumerate the many forms of treatment at present given at rate-supported and municipal institutions. The Poor-law hospitals gave excellent treatment, but the stigma of pauperism and administrative restrictions as to boundaries were objectionable. There was great need for additional beds in London for surgical cases—e.g., for rapid admission of cancer patients, for orthopædic cases, and for treatment of tonsils and adenoids. But there was not the same need for medical beds.

Coming to concrete proposals, Mr. Eason set himself to answer the questions put by Sir Arthur Robinson, of the Ministry of Health, to the British Hospitals Association. There was no definite line of demarcation, he said, between the types of cases to be treated by voluntary and by municipal hospitals. But as teaching hospitals must admit every type they would have a more rapid turn over and municipal hospitals would have a larger proportion of chronic cases. Each class of hospital must be equally well-equipped and prepared to tackle anything. Specialism had a narrowing effect and was inimical to well-balanced treatment. The shortage of beds was most serious for cancer, and next for orthopædic cases, whilst the shortage for throat beds could not be estimated till the medical profession made up its mind about the indications for tonsillectomy. The teaching hospital would be the "mother" of the group and the medical and nursing staff might be pooled. There would be a free transfer arrangement for patients from one hospital to another and the standard of treatment would be the same. The stigma having gone, the hospital-using public would soon learn there was no essential difference between the voluntary and the municipal hospital. In London the County Council could not possibly undertake the management of 104,000 hospital beds and might hand over the administration of all the hospitals to the present managers of the voluntary hospitals. The present "voluntary" management of institutions for venereal diseases, which were entirely paid for by rates and taxes, formed a precedent.

Mr. M. A. REYNARD (Glasgow Parish Council) began by expressing the opinion that the Poor-law hospitals in Scotland would have reached a higher standard if there had been a good lead from a central authority. Hospital accommodation in remote districts was quite inadequate. Glasgow had three Poor-law hospitals—Stobhill, the largest, had 1700 beds—and all three were used for teaching purposes. Coöperation with the other hospitals was good; for instance, they took in cases of pneumonia for the medical officer of health, post-encephalitics from all Scotland for the Board of Health, and about 40 maternity cases a week. There was no pauper stigma. The Glasgow practice could be applied to Scotland. The needs of remote districts might be met by cottage hospitals linked up with a central hospital by motor ambulances. The parish areas were obsolete; their populations varied from 300 to 596,000, and the small areas must go. The observation wards of the mental hospitals probably provided the most interesting material for teaching purposes. With the extension of the period of observation to six months there was now a 50 per cent. recovery-rate in these wards without certification. Small districts were apt to put individual needs before those of the community; for example, two neighbouring towns had recently each erected a 100-bed hospital, instead of combining to erect one more efficient 200-bed hospital. The Board of Health should say what and where hospitals were needed. Voluntary subscriptions were often not voluntary but extracted. He thought it would be fairer to put all the cost on the rates and assess each area proportionately. Homes for incurables were needed everywhere and, of course, did not require the expensive staffing of a hospital. Every hospital should have its convalescent home. The Glasgow convalescent home at Dunoon, empty for a time at first, was now always full.

Sir HENRY KEITH (Hon. Sheriff-substitute, Lanarkshire) doubted if the time for fusion was ripe. There was a strong trend towards coöperation. Certain types of disease were obviously more suited for rate-paid treatment. State grants were justified for teaching hospitals, as they were doing national work. Facilities for transport favoured small hospitals as much as central large hospitals, because the expert could be transported as easily as the patient. He thought the cost of small hospitals was less. (Several subsequent speakers disagreed with Sir Henry Keith and thought that when efficiency was considered large hospitals were more economical than small.) Scotland had proportionately more voluntary beds than England. Stobhill had lost its Poor-law stigma during the war. He would be inclined to leave the voluntary hospitals alone, meanwhile getting power, as in England, to subsidise with representation on the management, in the event of future financial difficulties. Local authorities could do much by combination at present.

Dr. J. P. KINLOCH (M.O.H., Aberdeen) showed how the problem had been practically solved in Aberdeen. After the war there was one 160-bed Poor-law hospital empty, while the voluntary and municipal hospitals needed beds. The Poor-law authorities had handed over the whole of their hospitals to the municipality and the municipality had handed over the medical staffing of these hospitals to the medical faculty of the university. The municipal and voluntary hospitals were complementary and not rivals. It did not matter to the medical profession who did the management as long as it was efficient. Voluntary hospitals could not provide heart, tuberculosis, and orthopædic schemes. Aberdeen encourages the voluntary hospitals. The various types of hospitals were pooled for the training of nurses.

Dr. H. B. BRACKENBURY (London) thought there was a danger of encroachment on the province of the general practitioner and the panel doctor by the hospitals and municipal authorities and that the shortage of beds was exaggerated.

Sir NORMAN WALKER (Edinburgh) agreed very largely with Mr. Eason and Mr. Reynard. As the result of a tour in Scotland he judged there was much coöperation in progress, both legal and illegal. The interests of patient and of teaching hospital were the same. Adequate provision for incurable cases was a crying need. The pooling of medical staffs, without legislation, would go a long way towards solving the problem. Small, medium-sized, and large hospitals must be linked up.

Dr. DRUMMOND SHIELS, M.P., remarked on the agreement between the speakers. The public liked the voluntary system, but did not like flag days and stunts. The voluntary system was being eaten in by semi-compulsory levies and payments which were not very different from rates. The difference between the two methods at present was more sentimental than real. His preference was for municipal hospitals.

Dr. A. S. M. MACGREGOR (M.O.H., Glasgow) believed that the provision of additional hospital beds tend

meet the needs of the general practitioner rather an to constitute an encroachment on his work. e thought the control of the Poor-law hospitals ken over by voluntary bodies would be a difficult atter.

Dr. STELLA CHURCHILL (London) deprecated the tablishment of special hospitals and thought the eal should be to have all the specialties in depart-ents of the general hospitals. She mentioned that appeal had recently been issued for £100,000 for new special hospital in London.

Dr. ARTHUR MANKNELL (Bradford) said the Bradford alth committee had leased St. Luke's Hospital om the guardians. It still acted as a Poor-law spital, but he thought there was a tendency to rry home the Poor-law and panel patients and to velop St. Luke's as an A1 general hospital in rivalry ith the voluntary hospital. The voluntary system as not by any means dead in Bradford.

Mr. EASON, in his reply, said there could be no ereotyped line of development for every part of e country. In London the question was, Would e County Council tackle the business or leave it experienced hospital administrators? The aching of the students was fundamental and there ust be freedom of thought and liberty of teaching.

Mr. REYNARD said that large hospitals were just economical as small and much more efficient. he pooling of medical staffs had been accomplished Glasgow.

Reviews and Notices of Books.

ENETIC STUDIES OF GENIUS.

Mental and Physical Traits of a Thousand Gifted Children. Second edition. By L. M. TERMAN and Others. London: Harrap and Co. 1926. Pp. 648. 21*s*.

The Early Mental Traits of Three Hundred Geniuses. By C. M. COX and Others. Same publishers. 1926. Pp. 842. 21*s*.

THESE two massive volumes are the first fruits an inquiry into the constitution and characters genius which has been organised by Prof. Terman Stanford University with the aid of the Common-alth Fund left by Mrs. Harkness. Of the importance understanding genius there can be no question, d we have here a serious and sincere attempt at e quantitative study of some of its aspects.

The first volume deals with the characters of about 00 "gifted" children selected by various pro-essive tests from many thousands of their school-llows, of whom they form a good deal less than per cent. at each age. They are compared through-t with a random sample of similar unselected ildren, and the "intelligence quotient (IQ)" is used a measure of their giftedness. The results are set t in sufficient detail for criticism. We can note re only some of the conclusions which are reached. e most gifted children fall outside the normal rve—i.e., they are not simply extremes of the rmal variation, but represent something which is her qualitatively different or so greatly differing in antity that it comes to the same thing. The gifted up contains a preponderance of boys and a marked cess of Jewish and Northern and Western European ck, and is drawn more from the higher than the wer occupational levels. In physical growth and neral health the gifted group is distinctly above the erage. Giftedness usually appears at a very early a, and is general rather than special in its scope. e most intelligent children read more and sleep re than the average, whom they also surpass in ts of honesty, trustworthiness, and similar moral its; they show no deficiency in play interests. ne of the conclusions are in accordance with eneral opinion," some are quite in contradiction. is important to note that they are derived from study of facts observed on a large scale with such quantitative accuracy as is at present available. It should also be remembered that they are statistical—i.e., they apply to the general mass of gifted children and not to each individual gifted child. As a whole they carry the distinct implication that nature is more important than nurture.

In parallel with this study of the Californian child of to-day, Dr. Catharine Cox and her assistants have worried out the early history of 300 eminent men, and have endeavoured to evaluate their childhood intelligence from the available biographical material. The ground is obviously rather insecure, but the tale she has to tell is of exceptional interest. And she derives the important conclusion that the extra-ordinary genius is also the gifted individual who may be discovered in childhood by intelligence tests. That all gifted children do not achieve high eminence is explained by the further deduction from her collection of case histories that geniuses who come to adult fruition are characterised not only by great intelligence in their youth but by persistence of motive and effort, confidence in their abilities and great strength of character. It means something, therefore, when Galton writes to his sister: "I am 4 years old and can read any English book. I can say all the Latin Substantives and Adjectives and active verbs besides 52 lines of Latin poetry," or when John Stuart Mill reads Plato at 7 and writes a history of Rome. If the conclusions of this book can be widely dispersed, such precocious monsters may perhaps get rather more sympathetic treatment than they are apt to have.

CLINICAL PEDIATRICS.

Edited by R. S. HAYNES, M.D., Clinical Professor of Diseases of Children, Columbia University, New York. Vols. VI.–X. London and New York: D. Appleton and Co. 1927. 16*s*. per volume.

THE first five volumes of this admirable system of pediatrics received notice in THE LANCET of Jan. 8th. The high standard of their predecessors has been well maintained by the five volumes which have now appeared, and which deal principally with disease in children of the pre-school and school ages. Vol. VI., by Prof. Willis Campbell, and Vol. VII., by Prof. J. A. Foote, are entitled Orthopædics of Childhood and Diseases of Bones, Joints, Muscles, and Tendons. These two volumes are to a large extent complementary to each other, and their contents are not altogether indicated by their titles. Vol. VI. contains an excellent account of orthopædic procedures in childhood, and also describes diseases of bones and joints from a surgical point of view, special attention being paid to the differences between the growing tissues of the child and those of the adult, and to the methods of preventing deformities in bony disease. Vol. VII. is written from the standpoint of the physician, and is devoted mainly to the constitutional and infective disorders of the organs of locomotion. Rickets and congenital syphilis receive due attention, and are particularly well illustrated by radiograms. In a chapter on helio-therapy, natural and artificial, the indications for the various types of apparatus are discussed. Vol. VIII., on the Digestive System, by Prof. F. C. Neff, is written in greater detail than those referred to above, and includes disturbances in infancy. Questions of ætiology and treatment of obscure conditions such as cyclic vomiting and cœliac disease are presented in a critical and well-balanced manner; the author reserves judgment also on the path of infection in pneumococcal peritonitis. In Vol. IX. Profs. W. L. Funkhouser and R. G. McAliley deal with diseases of the respiratory system. The account which they give of lobar and broncho-pneumonia is admirable, the difficulties presented by atypical cases being extremely well indicated. Empyema is treated rather shortly; all methods of evacuation are regarded as surgical and excluded from the account, and no reference is made to the distinction between syn- and meta-

pneumonic varieties. In the chapter on tuberculosis the preponderance of primary foci in the lungs at all ages is emphasised. Vol. X., by Prof. L. T. Royster, is concerned with the physiology of growth in normal children, and also with the pathology of malnutrition. The last chapters deal with nutritional and deficiency diseases, which leads to some overlapping with other volumes, as rickets and scurvy are included. An interesting chapter on acrodynia owes its presence in this volume to the author's view that this condition is a variant of pellagra rather than a toxic polyneuritis. These volumes are as attractive in appearance and as well illustrated as those of the first series. The practitioner, for whom it is primarily intended, will find in this system of pediatrics valuable help.

AIDS TO TROPICAL MEDICINE.

Third edition. By C. E. BROOKE, M.A., L.R.C.P. Edin., D.P.H., F.R.G.S., Chief Medical Officer, Singapore. London: Baillière, Tindall and Cox. 1927. Pp. 228. 4*s*. 6*d*.

BOOKS as handy and practical as this one are welcomed by workers in the tropics who require a ready and concise source of reference to supplement the larger text-books on tropical medicine. It is therefore unfortunate that it has several important defects. For example, some of the figures in the text are bad, and others inaccurate. The sections on treatment—as, for instance, of kala-azar—are inadequate even as a rough guide, and require amplification at the expense of history and pathology. It is necessary to point out that the treatment of paragonomiasis is not identical with that of bilharziasis. The proportion of space allotted to each subject is not always judicious. The classification of flies, mosquitoes, and even rats (to which 15 pages are devoted) is given in full, while that important parasite, *Filaria volvulus*, is entirely neglected. The terms diathermasia (page 49) and phoebism (page 151), which the author has coined for heatstroke and sunstroke, are inappropriate in a book of this nature, and the statement that *Bacillus coli communis* is responsible for "sporadic dysentery" is hardly accurate. The fact that so many workers in the tropics find this volume of the Aid Series useful makes it important that in a future edition these points should be considered.

PRACTICAL TROPICAL SANITATION.

Second edition. By E. P. MINETT, M.D., D.P.H., D.T.M. and H., Lecturer on Hygiene to the University of Hong-Kong; and A. G. M. SEVERN, M.A., M.D., D.P.H., Medical Officer of Health, Hong-Kong. School Notes by Mrs. MINETT, M.D., B.S., D.P.H., Assistant Medical Officer for Schools, Hong-Kong. London: Baillière, Tindall and Cox. 1927. Pp. 180. 5*s*.

THIS small manual is written as a pocket book for sanitary inspectors and others in tropical countries, and fulfils a useful purpose. The arrangement of the subject matter is simple; the manual deals with personal hygiene, water supplies, sewage and refuse disposal, food markets, abattoirs, mosquitoes, tropical diseases, buildings and construction, port sanitary work, disinfection, education regulations, and, finally, schools.

The information given is clear, accurate, and concise, while the illustrations and diagrams are excellent. The book deserves praise as a model of its kind, and is likely to be well received.

TEXT-BOOK OF BIOLOGICAL CHEMISTRY.

By JAMES B. SUMNER, Ph.D., Assistant Professor of Biological Chemistry, Cornell University, Ithaca, New York. New York: The Macmillan Company. 1927. Pp. 283. 15*s*.

THIS book provides a most interesting account of the general principles of biological chemistry. In an introduction the author summarises the aims and methods of the biological chemist, and points out their importance not only in medicine, but in clinical analysis, dietetics, bacteriology, and other fields. Biochemical reactions are explained, and an outline of the most important literature is given for the guidance of the elementary student. The book is divided into seven chapters, of which the first two contain fairly full descriptions of the fats and carbohydrates. Chapter III. summarises the question of acidosis. The proteins are dealt with in the next chapter, which includes accounts of the composition and general properties of these bodies. The tests for proteins are enumerated and described, and an account of the synthesis of polypeptides is given. Vitamins and the energy requirement are then explained, and in Chapter VII. urine constituents and their metabolism are dealt with in some detail. Then follow sections on the blood and respiration, physiological detoxications, enzymes, and the physical chemistry of protoplasm.

This small volume should be of great value to the elementary student. It is not intended as a book of reference, but forms an interesting summary of the principal facts and theories of biological chemistry.

Reports and Analytical Records

LACTREX: KING'S COMPOUND MALTED MILK FOOD.

(GEORGE KING AND CO., LTD., ALBION FOOD MILLS, SYCAMORE-STREET, E.C.1.)

Lactrex claims to be a starch-free food for infants from birth and for invalids. When analysed the following results were obtained:—

Moisture	3·54	per cent.
Ash	4·78	,,
Fat	19·00	,,
Protein	18·40	,,
Cane sugar	8·30	,,
Other carbohydrates including maltose, lactose, dextrin, and dextrose	46·00	,,

Starch was tested for with negative results. The reaction was slightly alkaline. The percentage of full-fatted dried-milk deduced from the fat content of the sample was 73, the balance consisting of malt extract and whey solids. When made up with water in the proportions directed the fat content approximates closely that found in cow's milk.

Lactrex is a well-prepared food and pleasant to the palate. The fat content, freedom from starch, and ready miscibility with water are undoubtedly points in favour of the use of this food for infants.

BUCKFAST TONIC WINE.

(MADE BY BENEDICTINE MONKS AT BUCKFAST ABBEY. SOLE DISTRIBUTING AGENTS: J. CHANDLER AND CO. (BUCKFAST, LTD.), 41–42, PARLIAMENT-STREET, S.W. 1.)

It is claimed that the wine is made from the choicest and finest of natural tonic wines to which are added medicinal ingredients of a health restoring and therapeutic character. It is indicated for the treatment of anæmia, nervous exhaustion, and debility. On analysis the following results were obtained:—

Alcohol by volume	15	per cent.
Equivalent to proof spirit	26	,,
Total acidity as tartaric acid	0·26	,,
Volatile acidity as acetic acid	0·01	,,
Total extract	23·26	,,
Consisting of—		
Invert sugar	21·3	,,
Mineral matter	1·25	,,
Protein	0·34	,,

From these results it will be seen that Buckfast Tonic Wine is of the port type with rather less alcohol and considerably more sugar than is usual. The protein, if calculated to meat extractives, would be equivalent to 0·5 per cent. The wine possesses a good palate and is free from preservatives.

THE LANCET.

LONDON: SATURDAY, AUGUST 6, 1927.

THE BRITISH-AMERICAN NEUROLOGICAL MEETING.

LAST week the American Neurological Association and the Section of Neurology of the Royal Society of Medicine held a joint meeting in London, and the event deserves notice even in these days of world travel and of congress multiplicity. For this was the first occasion on which a British-American gathering of neurologists has taken place, and it becomes us to put on record our appreciation of the compliment our American confrères paid us in coming so far (many of them having travelled long distances before reaching the Atlantic) and with such a comprehensive representation of American neurology, to attend a three-day meeting. From the very beginning, the reception by Sir JAMES and Lady BERRY at the house of the Royal Society of Medicine, a note of cordiality was struck, and as the congress proceeded it deepened into one of mutual regard and of personal good-fellowship. While some of the older neurologists of the United States were missed, they were nevertheless worthily represented by the veteran Dr. CHARLES DANA, to whom was given the honour of delivering the Hughlings Jackson lecture, and who performed his task with distinction. An abstract of this lecture and of the discussions as a whole will be found on a later page. The contributions from the younger members of the American Neurological Association were remarkable for the high general level of knowledge and research which they revealed, and they furnished impressive evidence of the standard of attainment which American neurologists have set themselves. Of the existence of this scientific spirit of inquiry and study the chance visitor to American schools of medicine and to American medical conferences has long been aware, but when one of their medical societies (with limited membership, it is true) comes over to offer its contributions to an audience the major portion of which is English, and when one presentation after another forms a fine addition to neurological theory or practice, the effect is undoubtedly highly impressive. Who knows whether the tide of research will not set westwards more strongly than ever, as a sequel to this boldly conceived and admirably executed idea of showing an assembly of our English neurologists what American neurology is doing?

Naturally, we shall not with false modesty underrate the value of the contributions of the former to this successful joint meeting, the more so as in many instances they were of outstanding merit, and were generously pronounced to be so by our American visitors. The truth is that contact of mind with mind arouses emulation and yet leads to the cultivation of reference, and in this respect the discussions of last week must prove eminently fruitful. Criticisms were friendly and controversies were eschewed, as befitted a meeting of two English-speaking races. At the banquet which was the official close of the conference the toast of "Coöperation in English and American Medicine" was surely honoured not only by outward signs, but by mental resolve on the part of guests and hosts that it should stand for a reality to-day. Possibly one of the greatest delights in a joint gathering of this kind resides in the opportunity it affords of seeing and hearing men whose names have been familiar, through the medium of printed contributions, to neurological doctrine. Many of those visitors who crossed the sea to meet us were known by reputation, and it is a charming experience to come into personal contact with medical confrères animated with the same ideals as ourselves and interested in the same subjects; even if imaginary impressions are corrected the end-result is never a loss. Beyond the manifest significance of these gatherings lies a latent and deeper meaning. It is embodied in the idea that this is the only kind of interracial rivalry a war-sick world can bring itself to tolerate—in the case of medical men, an amicable struggle to attain the end of perfect knowledge of the ills of the flesh and to achieve the consummation of the art of healing. In the realm of medical science racial isolation is more than ever an impossibility. Any steps which are taken from time to time to impress this fact on collective medical consciousness will always be welcome. A natural outcome of the British-American Neurological Congress is the hope, publicly expressed by our visitors, that in two or three years a return meeting may be organised on the other side of the Atlantic. A precedent is established with conspicuous success, and it may find an echo in other similar conferences of English-speaking specialists. This would indeed be the best compliment that could be paid to the organisers of the neurological meeting that has now become a pleasing memory.

MEDICAL OFFICERS AND PUBLIC SCHOOLS.

IN April last a memorandum, with a series of recommendations, was published in the Supplement of the *British Medical Journal* dealing with the conditions under which the work of a medical officer of a public school is carried on, and enumerating the circumstances in which the duties and responsibilities differ from those of the general practitioner. The origin of the memorandum lay in the fact that the Medical Officers of Public Schools Association had sought the assistance of the B.M.A. with a view to secure improved conditions in their employment and remuneration, feeling that their status required definition and that their prospects called for improvement. The memorandum was a very detailed piece of work, as all will see who refer to it,[1] for the paragraphs nearly exhaust the alphabet, and these are followed by 19 recommendations, 13 having reference to the work of the whole-time medical officers of public schools and the remainder dealing with the part-time officers. It can be said that the matter has been looked at from every side in the interests of the doctors.

At the recent Representative Meeting a report with this series of recommendations was introduced for adoption by Dr. J. W. BONE, Chairman of the Medico-Political Committee, who admitted that the Association was leaving its ordinary routine in its proposed action, opening up a whole new class of work; but he urged that this was being done at the instance of representations from the whole-time medical officers of public schools, and in the event it was seen that the Representative Body declared themselves ready to deal with the matter. A preliminary debate took place as to the advisability of any such discussion among the Representatives before an arrangement or approach for a preliminary understanding had been arrived at with the governing bodies and headmasters of public schools, and, moreover, it was evident that

[1] Brit. Med. Jour., April 23rd, p. 149, Sup.

each policy, that of going forward and that of pausing, could be soundly supported. Unless the Association had formulated its views already there could be nothing concrete to put before the governors and the headmasters; but unless the school authorities and headmasters were invited to collaborate from the first they might be unwilling to join in a conference whose terms of reference had never been placed before them. The meeting in the end—and wisely, we think—decided to go into committee, with a view in this way to get the opinion of the Representatives broadly upon certain propositions; after which the whole matter could be taken back to the Council of the Association for the conduct of further negotiations. In committee accordingly Dr. BONE moved the most critical of the recommendations contained in the report—namely, that the whole-time medical officer of a public school should be appointed by, be directly responsible to, and have direct access to, the governing body of the school. The recommendation was carried unanimously, and here at any rate we may surmise that all modern educational bodies will be in accord. To make the man who is to be responsible, with the coöperation of all the members of the teaching staff, for the health of the pupils an integral part of the organisation of the school is only logical if—and this is provided for in the Recommendations—the method of election secures an officer whose training and experience fit him for the post. But there will be many things to be discussed in detail, though already some of the great public schools may be inclining towards a policy which has everything in its favour.

The duties which such an officer would have to discharge—speaking in terms of the public school for boys—are many and different, and call for a display of wisdom in various shapes as he comes into touch with the head-master, the teaching staff—especially the house-master, and the boys. He will be responsible for the examination of the new pupils, and the scrutiny of these before admission should be as well organised and as thorough as any entrance examination in respect of educational standards; in fact the physical tests call for greater care as being more difficult of application. At this point he will have the advantage, if and where needed, of coöperation with the pupil's family doctor, but thereafter he will be solely responsible for the boy's health when at school, and from the point of view of isolation he may be at a disadvantage in his clinical practice which is not shared to-day by many of his colleagues in general practice. He must be prepared to make periodical examinations of resident pupils with as much method and particularity as the teaching staff display in their periodical stock-takings of educational progress; it is at least as important that at a given age a boy should have reached appropriate physical development and be bearing the strain of growth equably, as that he should be in a form with his coevals and be holding his own among them. How to obtain the most trustworthy results of physical examinations will call for a real knowledge of boys and an understanding of the part which games play in the world of school. And while it will be his duty to observe, in the interests of staff and pupils alike, that the general sanitation of the school is good, he will also have to supervise and inspect the dietary, when there may be occasion for the display of genuine tact in his relations with his colleagues on the teaching staff. And when it is added that much of this carefully planned work must be the subject of detailed note-making and written reports, enough has been said on general lines, without going into exact definition of clinical procedure, to show that such an officer should be selected in the most careful manner and on indisputable grounds for his fitness both in character as well as in attainments. He should owe his appointment to central authority to which he should make a regular report; and while thus removed from the risks of mere personal bias he should receive suitable payment for his services. The memorandum of the Association should be circulated to the governing bodies and teaching staffs of the public schools—to a selected group of large institutions in the first place—and their criticism invited. It is clear that all the recommendations will not be acceptable to all the schools, but the main principles should find immediate favour because of their public effect. A basis would thus be obtained upon which fruitful action could take place; for in the words which are the best argument for reform "Something has got to be done."

CANCER OF THE UTERUS.

To refuse to look unwelcome facts in the face even when knowledge may bring relief, is a deeply ingrained habit of the human mind. Its extent and its tragic consequences are illustrated by the plain tale of figures amassed by Dr. JANET LANE-CLAYPON [1] in her survey of the results of treating cancer of the uterus. In 51 per cent. of the women who applied for treatment of cancer of the cervix it was no longer possible to undertake radical operation, and on the average, according to their own statement, these patients had had symptoms for six to nine months before attending hospital. Dr. LANE-CLAYPON points out that as the natural duration of the disease from the onset of symptoms to death in untreated cases is about 21 months, the delay of six to nine months is largely accountable for the high proportion of inoperable cases. To this toll of this avoidable waste must be added many years of life lost by an unknown number of women who never come for treatment.

This is only one of many points brought out by the report. Periodical balancing of the account in all available records is essential for any clear grasp of the practical results of our knowledge and treatment of disease, and it is equally obvious that in this particular case the mere volume of the scattered literature makes this balancing almost impossible for most medical men, particularly, perhaps, for those specialists to whom it is most useful. The Ministry of Health is to be congratulated in taking up this task and in having found in Dr. LANE-CLAYPON a worker able and willing to assimilate the mass and to reproduce the essential information in a form in which it is readily available for the use of the profession. The data are taken from 848 papers derived from 16 different countries, and cover some 80,000 cases of disease. Yet the main facts have been clearly given in 59 pages of text backed by 76 of tables. To summarise such a summary would do the subject little justice and we recommend those who are interested to study the report for themselves. A few of the salient points may, however, be mentioned mainly to indicate its scope. Cancer of the cervix and of the body of the uterus are as far as possible considered separately. In cancer of the cervix the relative advantage—as measured by the survivorship at the end of five years—of treatment by abdo-

[1] Reports on Public Health and Medical Subjects. No. Cancer of the Uterus: A Statistical Inquiry into the Results Treatment, being an Analysis of the Existing Literature. Janet E. Lane-Claypon, M.D., D.Sc. Ministry of Health. 19 3s. 6d.

inal hysterectomy and radiation depends on the nclusion or exclusion of cases judged to be inoperable n application. If these are excluded, abdominal ysterectomy has the advantage with 37·6 per cent. f survivors as against 35·8 per cent. If inoperable ases are included the advantage lies with radiation hich gives a survivorship of 22 per cent. as against 8 per cent. Radiation thus offers an expectation f life of at least five years to 12 per cent. of the ases deemed inoperable. With all forms of treatent early cases show a mortality about half as arge as that of the more advanced borderline cases, nd the improvement shown by the later records of ndividual clinics shows the importance of specialised kill and knowledge. The figures are also analysed rom the point of view of age, marriage, and childearing, and some lend themselves to discussion of solated pathological points of interest. Fewer data re available for cancer of the body of the uterus han for cancer of the cervix. The mean age of ccurrence in this site was eight years later and he mean average duration of symptoms before pplication for treatment was 18 months. Abdominal peration gave more favourable results in this site han in the cervix, but as is already recognised the esults with radiation are here definitely less favourable han those of operation.

Those who recognise the value of this series of tudies and who are themselves engaged in the reatment of cancer may be reminded that systematic ecords and some method of following up cases may ake their skill bear fruit beyond their own practice. On this point we may quote Sir GEORGE NEWMAN n the introduction to the report:

"Unfortunately," he says, "it is difficult to ascerain the exact extent to which radiation is used in England; still more difficult is it to obtain a knowedge of its results, owing to the apparent and natural isinclination of surgeons and radiologists to publish ccounts of series of cases. This in turn is no doubt ue to the absence or incompleteness of clinical ecords and of a system for ascertaining the afteristories of treated patients. Such indications as re available seem to suggest that we are much less dvanced in the treatment of cancer by radium than ertain continental countries, and probably keep ess satisfactory records. If these impressions are onfirmed, by the acquisition of further evidence, he position is one for some disquietude and for a erious and sustained effort to remedy the defects."

Apart from any possible improvement in treatent an immediate duty seems to be to drive home o the general public the danger of delay. In the words of FRANCIS BACON: "There is surely no greater isdom than well to time the beginnings and onsets f things. . . . Nay, it were better to meet some angers halfway, though they come nothing near, han to keep too long a watch upon their approaches."

NEED FOR MORE DENTAL CLINICS.—Prof. W. H. ilmour, of the University of Liverpool, in his presidential ddress at the annual meeting of the British Dental Assoiation on July 29th, deplored the fact that owing to the umbers requiring treatment in the school dental clinics nd the comparative scarcity of dental officers, millions f teeth were lost because they were not treated at the nception of caries. Additional school dental clinics were eing set up all over the country and there were 289 wholeme and 355 part-time dentists now employed in this ork. The service was equivalent to that of 354 wholeme officers, but to provide one dentist for every 5000 hildren in elementary schools the number needed would e 1600. For Liverpool's 134,570 elementary schoolhildren there were only five full-time dentists. The ideal ounded costly, but it would be nothing compared with the enefits which would accrue from a general contentment if ood health were established and pain eliminated.

Annotations.

"Ne quid nimis."

NOTIFICATION OF INDUSTRIAL POISONING.

THE Chief Inspector of Factories has issued a circular (Form 304) calling the attention of medical practitioners to their obligation to notify him of industrial poisoning contracted in a factory or workshop. The list of notifiable conditions now includes poisoning by lead, phosphorus, arsenic, mercury, carbon bisulphide and aniline, chronic benzene poisoning, anthrax, toxic jaundice, epitheliomatous or chrome ulceration. The practitioner is also required to notify lead poisoning contracted during the painting of a building whether or not that building is a factory or workshop. Notification is to be made on the form provided, which includes a twofold expression of opinion (1) that the patient is the subject of one or other of the diseases or forms of poisoning enumerated, and (2) that the practitioner believes the poisoning to have been contracted in a factory or workshop or in connexion with the painting of a building. Doubt may arise as to the actual employment of a plumber, but, as he generally spends some portion of his time dealing with lead material in a factory or workshop occupied by his employer, notification should be made. Recurring attacks in the same subject require re-notification if the affected person has continued at work, although not in the case of persons with chronic poisoning who have ceased work. The term aniline poisoning is intended to include the hæmolytic action of red blood cells to which the term anilism has been given. Chronic benzene poisoning takes the form of aplastic anæmia when small quantities of benzene are inhaled over a prolonged period. Notification of poisoning contracted otherwise than under the circumstances specified is not demanded, the reason given being that it would be incomplete and therefore useless for statistical purposes. Forms of notification will be supplied on application to the Chief Inspector of Factories, Home Office, London, S.W. 1. A fee of 2*s*. 6*d*. is payable for any such notification.

THE ROSS INSTITUTE.

IN the first annual report of the Ross Institute, issued since its opening by H.R.H. the Prince of Wales on July 15th, 1926, there is a record of some of the Empire-wide antimalarial work which is at present in progress. The visit of Sir Ronald Ross to Ceylon [1] has now been followed by one undertaken at the invitation of the Indian Tea Association. By the proverbial hospitality of the East, the tour was enlarged to include Malaya, with its pioneer work by Sir Malcolm Watson, before reaching Calcutta and Assam by way of Burmah.

Upon this visit Sir Ronald Ross has issued a separate report which, in clear language, places his conclusions at the disposal of the Institute which made his tour possible. The report lays emphasis upon aspects of the malaria problem which are perhaps too little appreciated even by medical men. A good example lies in the difficulty which the villainous plasmodia normally experience in reaching a fresh host; if the statement runs on the lines of the well-known nursery legend, it is none the less an actuality. Only a fraction of the many anopheline species transmits malaria; only a fraction of the eggs of potential transmitters reaches adult maturity; only a fraction of these adults bites malaria cases; only a fraction of these malaria cases is infective; only a fraction of the infective cases infects mosquitoes; only a fraction of the infected anophelines survives to become potentially infective for man; only a fraction of men bitten by infective mosquitoes becomes infected. The odds, then, against plasmodia maturing in fresh hosts are very

[1] THE LANCET, 1923, ii., 962.

heavy, and malaria can flourish only when anopheles and plasmodia abound—a sustaining thought for the sanitarian who finds that he has failed to exterminate anopheles or plasmodia. He knows that if he can sufficiently lower the numbers of one or both, there will come a point, as is the case now in England, when malaria will cease to be the industrial menace which it still is in the tropics.

When balancing the financial gain of efficient labour against the financial expenditure in anti-malarial effort, Sir Ronald sums up the matter thus: "Both malaria and malaria control cost money; but the former costs health and even life itself in addition," a pregnant sentence which indeed contains the entire justification for all sanitary services in all countries. His suggestion that planters would find the issue, with obligatory use, of mosquito nets to their coolies a "profitable charity," and his comment upon the effect of "congregate sleeping" on the rapid spread of infection and reinfection, and upon the value of the building of proper coolie lines, all add weight to the finding of the Near East Malaria Commission of the League of Nations—that malaria is a house infection, and that the proper place to attack the mosquitoes concerned is in the home itself. Of localities visited, pride of place is given to Singapore, on the ground that in no other city in the British Empire has, it is believed, malaria control so progressed or been so enthusiastically carried out, every step being preceded, as is unhappily not always the case, by entomological and engineering surveys. In Calcutta, Sir Ronald Ross witnessed the unveiling, by Lord Lytton, the Governor of Bengal, of the handsome Gate of Commemoration which leads to the little laboratory, situated in the spacious grounds of the Presidency General Hospital, where he worked in 1898. In Assam much keen antimalarial work is being done in certain tea gardens, little in others. The main malarial need of the Province, it is held, is not so much the will to move, as is the case in Burmah, but an organisation on the lines of Malaya. This would be effected by the institution of local Malaria Control Boards, which could exercise persuasion or compulsion on those who bring to nought their neighbours' expensive antimalarial work. A final word deals with the 1987 Indian antimalarial societies which already exist, apparently in Bengal only, under the skilled and enthusiastic initiation and direction of Rai Bahadur Dr. Copal C. Chatterjee. They are of primary importance, not only for what they have done for the villages in which they have been established, but for the evidence which they offer of the growth of the spirit of self-help which it is a main function of the British administration in India to foster.

Sir Ronald Ross has just been awarded the gold medal of the African Society for the best work done on behalf of the African continent. It is not given to many to experience, in their lifetime, even the initiation of a permanent memorial to their life-work other than the work itself. Sir Ronald Ross is happy in this, and it would be most fitting that he should see the Ross Institute set, as it is not at present set, upon an abiding basis.

RECTAL ETHER ANALGESIA IN LABOUR.

IN a paper read before the last annual meeting of the American Association of Obstetricians, Gynæcologists, and Abdominal Surgeons, Dr. J. A. Harrar[1] stated that the Gwathmey method of producing analgesia in labour had been used at the New York Lying-in Hospital in 5800 cases during the last three years with very satisfactory results. The drugs required were morphine sulphate, magnesium sulphate, quinine, and ether. Morphia gr. ¼ was given hypodermically with 2 c.cm. of a 50 per cent. solution of magnesium sulphate to prolong its action. Half the quantity of ether required for surgical anæsthesia (rectal administration) was dissolved in 4 oz. of oil with gr. 20 of quinine alkaloid, and was instilled into the rectum as a retention enema one to four hours after the morphia and magnesium sulphate had been given. When the effect of the first instillation had worn off and the patient again complained of pain which was usually in two or three hours, a second or even a third rectal instillation of ether might be given at intervals of three hours or more. In 85 per cent. of the cases pain was greatly relieved. There was no prolongation of the perineal stage or increase in the number of forceps deliveries. The only contra-indication to the procedure was uterine inertia and the only restriction was not to start too soon. The patient should be in active labour with pains every four or five minutes, and in a primipara the cervix should have attained a dilatation of two or more finger-tips. Dr. Harrar claimed that the applicability of this method was much greater than that of scopolamine amnesia, as it could be used safely and effectively by the practitioner in confinements at home and did not require the services of a trained anæsthestist.

TUBERCULOSIS AMONG NURSES.

A FEW years ago Dr. Olaf Scheel, chief of one of the divisions of the Ullevaal communal hospital in Oslo, drew attention to the serious frequency with which nurses, especially when on probation, contracted tuberculosis. Was this high tuberculosis rate, he asked, the result of massive infection of persons who, coming from the country, had acquired no immunity to tuberculosis, who were, in other words, Pirquet-negative; or did the strenuous life of the probationer make some old tuberculous focus flare up? Or were there other factors at work? He decided to carry out Pirquet tests systematically, and the very interesting and, to a certain extent, unexpected results of these tests are published in the June number of *Norsk Magazin for Laegevidenskaben*, by Dr. Heimbeck. From Jan. 1st, 1924, every nurse was tested with concentrated old tuberculin when starting work, and the Pirquet test was repeated from time to time on those whose reaction was negative. Of the 397 probationers thus examined 208 gave a negative, 189 a positive reaction. A classification of the nurses according as they came from (*a*) the country, (*b*) country towns, and (*c*) large towns, showed that, of the 132 in the first category 82 were Pirquet-negative; of the 116 in the second category 60 were Pirquet-negative, and of the 148 in the third category 66 were Pirquet-negative. After discussing possible explanations of this high proportion of negative reactions in persons between the ages of 20 and 30 (extraordinarily high for the town-dwellers) Dr. Heimbeck refers to two other recent Norwegian series of Pirquet tests in young adults, in both of which about half the number of persons examined were found to be Pirquet negative. The subsequent fate of the nurses, classified according as they were Pirquet-negative or positive, was more instructive. Since January, 1924, as many as 43 developed signs of tuberculosis (6 cases of pulmonary disease, 16 of pleurisy, 3 of tuberculosis of the bones and glands, and 18 of erythema nodosum), and 40 of them were Pirquet-negative when they entered hospital as probationers. All the 18 nurses suffering from erythema nodosum gave a markedly positive Pirquet reaction after the skin eruption had appeared. Among the 51 nurses who were Pirquet-negative in 1924 there was only one of those still nursing in the hospital who remained so; the rest had become Pirquet-positive. Of the 72 Pirquet-negative nurses belonging to the probationers of 1925 two remained Pirquet-negative. Of the 62 Pirquet-negatives of 1926 only 18 were so still in 1927. Having come to the conclusion that a negative Pirquet reaction indicated susceptibility to tuberculosis, and a positive reaction the reverse, Dr. Heimbeck argued that if the Pirquet-negatives could be converted to Pirquet-positives by a mild infection, such as that induced by inoculation with Calmette's B.C.G. vaccine, a certain degree of immunity to tuberculosis might be acquired. Instead of giving the vaccine by the mouth, as recommended by Calmette in the case of infants, he

gave it by subcutaneous injection, a dose of 0·05 mg. repeated in some cases after a week's interval), being found after some preliminary tests to be the most suitable. The Pirquet reactions of these nurses became positive. But it remains to be seen whether they have been effectively immunised against tuberculosis or not.

THE RETIREMENT OF MR. F. G. HALLETT.

IT was announced at the Comitia of the Royal College of Physicians of London, held on Thursday, July 28th, that Mr. F. G. Hallett had expressed a desire to retire in December next from the post of Secretary to the English Conjoint Examining Board. Mr. Hallett joined the office staff of the Royal College of Surgeons of England in 1877 and became assistant secretary to the College five years later. In 1886 he was appointed secretary to the newly constituted Conjoint Board and has completed, therefore, 50 years' service at the College and with the Board. We are glad to know that recognition of this long and arduous service is to be reflected in the arrangements made for pension, but neither capital sum nor annual life payments can really express the debt which the medical profession owes to Hallett's long and wise labours. He devised arrangements for the examination conducted by the Board which were equally directed to the advantage of examiner and examinee, and made the scheme of the Board an example, in principle and detail, to all educational authorities having the duty to set up qualifying tests of medical knowledge. Only those who have come into personal touch with him can be aware of the amount of personal trouble as well as organising power expended by Hallett in the conduct of the examinational routine of the Conjoint Board; he will take with him into retirement a wide wish that he should live long to enjoy leisure.

PROPHYLAXIS OF OPHTHALMIA NEONATORUM.

IN a paper by Mr. A. E. Iles [1] the diminution of the number of notified cases of ophthalmia neonatorum in Bristol from 15·7 per 1000 births in 1922 to 8·3 in 1925 is attributed to three causes: (1) training and registration of midwives; (2) increased use of Crédé's method of prophylaxis; and (3) compulsory notification, leading to early treatment. The figures may be compared with those of London where (under compulsory notification) the incidence increased during the four years from 7·75 per 1000 births in 1914 to 10·37 per 1000 in 1919; of Leeds, where the proportion in 1919 was 13 per 1000, and of Glasgow, when in 1913 the ordinary definition of ophthalmia neonatorum was extended to include any inflammation of the eyes accompanied by discharges occurring during the first 14 days of life, with the result that the rate of disease was raised at once from 9·6 to 12·6 per 1000 births.[2] This last fact points to a possible fallacy underlying some of the foregoing figures. In the post-war years in Glasgow, according to Dr. Freeland Fergus's computation, the incidence of gonococcal cases fell from 10·3 per 1000 births in 1919 to 2·9 in 1924, a very remarkable decrease, but one which there is reason to believe is not confined to Glasgow. The same tendency appears in America. From statistics of the disease in Newark, a city of some 450,000 inhabitants, Dr. Julius Levy concludes that there was an increase in ophthalmia in the three years following the war, and that there has been a very marked and rapid diminution in the number of cases of ophthalmia in the last three years.[3] It seems highly desirable that a systematic comparison of the incidence of the disease in different cities in recent years under parallel conditions of notification (and either all including or all excluding cases not due to the gonococcus) should be undertaken. So far as we are aware this has not been done. With regard to prophylaxis, several writers have pointed out that the routine use of silver nitrate drops in a concentration of 2 per cent., as originally recommended by Crédé, is followed in a considerable proportion of cases by an undesirable reaction, and it is now generally recommended that the strength used for prophylactic purposes should be 1 and not 2 per cent. Mr. Iles recommends a 1 per cent. solution of mercurochrome, a compound of mercury and fluorescine, which he believes to be safer than silver nitrate, as it hardly ever gives rise to reaction.

THE FOOD OF THE JAPANESE.

IT is interesting to study the food problems of a practically homogeneous race which is changing from an agricultural to an industrial character. A great deal of work has been done by the medical staff of the Japanese Army on the dietaries adapted to their countrymen when doing light, moderate, and heavy work, and recently Prof. Shozo Toda, of the Kyoto University, has discussed in the *Japan Medical World* the actual consumption of food in Japan. Japan is one of those fortunate countries which produce nearly all the food they need. Some rice, beans, sugar, eggs, and wheat flour are imported but very little else, the total excess of food imports amounting, it is believed, only to about 11 per cent. of the nation's requirements. It is calculated by Prof. Toda that the mixed population of Japan, 56 million in all, requires the same amount of food as 43 million adults. After careful inquiry of rural and urban government authorities he has corrected the statistics of food production and consumption, which would appear, it may be said, very greatly to underestimate the production of vegetables other than cereals and fruits. The kitchen utilisation of this corrected food consumption yields figures which agree very closely with Colonel Koidzumi's results on actual feeding experiments alluded to above. The following table shows this:—

Daily Consumption of Food in Japan Expressed in Grammes (Percentage of Total in Parentheses).

	Statistical.	Estimated actual.	Army metabolism experiments.
Protein ..	98 (15) ..	120 (15) ..	95 (14)
Fat ..	16 (5) ..	20 (5) ..	19 (6)
Carbohydrate ..	570 (80) ..	670 (80) ..	545 (80)
Calorie value ..	..	2900 ..	2800

These values when compared with Voit's scale show a marked deficiency of fat, even when allowance is made for the relative weights, 70 kg. and 50 kg., of the average German and Japanese adult men. The ratio of physiological demands of food calories of the European and Japanese are 100 : 85, based on weights and body surfaces; and on this basis the Japanese eats more than the European, this being mainly due to the large proportion of rice consumed in Japan. This cereal appears to be very digestible in all respects, and although poor in protein and very poor in fat, especially meets the taste of the Japanese. The protein consumed by the European is largely derived from land animals, whilst the Japanese relies mainly on fish, in so far, that is, as he consumes animal food. Although the consumption of fish is going up, "the modern urban people in Japan are inclined to take a simple food of polished rice with some subsidiary diet. . . . This monotony of dietary produces malnutrition. . . . Moreover, it seems to be a chief cause of the increase of beriberi." The growth of population has been approximately proportional to the production of rice. Disease or a higher rate of mortality does not seem to follow a poor rice year but crime does. The present position of Japan is not favourable to cattle raising on a large scale, but larger catches of fish might easily be made and something done to use a greater proportion of the total catch for food and less for manure. The problems of a population which has so rapidly altered its habits must in the nature of things be difficult.

ISAAC NEWTON: A MEMORIAL VOLUME.

IN this year falls the bi-centenary of Newton's death; and in January, 1926, the council of the Mathematical Association suggested that the occasion should be commemorated by a special number of the *Mathematical Gazette*. Finding, however, that the matter would far transcend in quantity the limits of a single number of the *Gazette*, the council decided to issue the volume as an independent book.[1] Its contents, as might be expected, are for the most part essays on abstruse mathematical subjects, written by eminent mathematicians and chemical physicists, and are considerably beyond the understanding of the general reader; but some of the papers deal with subjects which are not only of interest to experts but can also be enjoyed by any one who has had some training in the physical sciences. For instance, the second paper, by Prof. H. E. Armstrong, on the Forms of Carbon and Chemical Affinity, should be read together with Sir William Bragg's two charming books, Concerning the Nature of Things, and Old Trades and New Science. Newton was an enthusiastic chemist, and was also deeply interested in optics and the phenomena of colour. At first sight it would seem that carbon and colour have nothing to do with each other, but anyone who reads Prof. Armstrong's paper will find that they have, at least in so far as substantive colour goes, for in Prof. Armstrong's words, "colour appears to be the outcome of an effect exercised at absorbing centres of an ethenoid character." Prof. A. R. Forsyth contributes a paper upon Newton's Problem of the Solid of Least Resistance. The problem, as Newton recognised, has direct bearing upon the forms of ships; Newton's postulates have not, however, stood the test of modern research, although they led to Froude's experiments, begun about 1870. For the general reader the most interesting paper is that contributed by Prof. D. E. Smith, consisting of two unpublished documents by Sir Isaac Newton; these are a notebook written when he was about 17, and a proposal for a commission to prosecute coiners and counterfeiters, written when he was Master of the Mint, about 1699. The documents are in Mr. Pierpoint Morgan's library. The notebook contains sundry recipes, including some which are medical. Other papers deal with Newton and his homeland, by Mr. J. A. Holden, M.A., master of the King's School, Grantham; and Trinity College in the time of Newton, by Prof. G. N. Watson. The book is excellently illustrated, and altogether is a compilation worthy of its subject.

ULTRA-VIOLET RADIATION AND RESISTANCE TO INFECTION.

THE curative effects of radiation in rickets and surgical tuberculosis, the well-known bactericidal action of ultra-violet rays, and perhaps an instinctive association of sunlight with good health, have led to a widespread assumption that man's resistance to many if not all forms of disease may be increased by actinotherapy. In a clinical study of one aspect of this hypothesis Dr. Claire M. Hill and Dr. Janet H. Clark have tested the possibility of increasing the natural resistance of rats to pneumococcal infection. In the *American Journal of Hygiene* (July, 1927) they give full details of a thorough investigation of this problem, together with a short survey of the other clinical and experimental work which has a direct bearing on it. Considering the difficulty of estimating and expressing ultra-violet dosage and the variety of infections studied it is not surprising that they have found the available data contradictory. Certain sequelæ of ultra-violet radiation appear to be definitely established, such as the leucocytosis with relative increase in the lymphocytes, an increase in the number of blood-platelets, and a transient increase in the bactericidal power of the blood as tested on certai cocci by the slide-cell method. These changes in th blood seem to be compatible with an increase resistance to infection, but they cannot be regarde as proof of such an effect. Against the belief tha ultra-violet rays have any such beneficial action is th report of L. H. Barenberg, I. Friedman, and W. Green who are quoted as having tested prophylactic radiatio with the mercury-vapour lamp on a large number c children in an institution during the winter month Daily radiation failed to reduce the incidence of th usual febrile and respiratory infections, from which th irradiated children suffered rather more than th control group. The experiments of Dr. Hill and D Clark were designed to test the possibility of increasin resistance to pneumococci of Group I. in a colony c inbred albino rats under varied but rigidly controlle conditions. It was found that small doses of ultra violet rays did not affect the rate of growth of the rat but large doses resulting in severe burns were associate with relatively slow growth. The only constan change in the blood was an increase in the blooc platelets, but this could not be correlated wit increased resistance to infection. Daily irradiation f two or three weeks seemed to give rise to a slight increased resistance to subsequent infection, bu irradiation after infection was without demonstrab effect. They conclude that in the present state of o knowledge there is little justification for the use ultra-violet rays as a general therapeutic agent infectious diseases, and that there is very little suppo for the belief that actinotherapy can increase t resistance of normal individuals to infection.

CONGRESS ON OCCUPATIONAL DISEASES.

THE Permanent International Committee on Occ pational Diseases having decided to abstain from t congress called by Hungary in 1928 has just instruct its members of French nationality to organise the Four International Session which will take place at Lyo from April 3rd–6th, 1929. The questions on the agen are as follows: 1. Silicosis (three reports: ætiolog clinics, and legislation); a general report dealing wi forms of pneumoconiosis. 2. Cataract of occupatio origin (two reports: ætiology and clinics). 3. End crine system and forms of poisoning (it is intended furnish under this heading a single report to e entrusted to three experts). 4. Communicatio relating to results of inquiries so far unpublish If it is found advisable to include another question the agenda the subject chosen will be the problem occupational disease statistics.

Prof. Etienne Martin, of the Institute of Le Medicine of Lyons, in collaboration with Prof. Agas Lafont and Prof. Kohn-Abrest, of Paris, with approval of the executive, will designate the expe selected to present reports on the subjects before Session. Requests for all further information sho be addressed to Prof. Etienne Martin, or to Secretariat of the Committee, Hygiene Serv International Labour Office, Geneva.

THE death is reported of Dr. Rudolph Magn professor of pharmacology in the University Utrecht.

Dr. Robert Howden has resigned the chair anatomy in Durham University, which he has h for a period of 38 years.

Sir Hugh Anderson, Master of Gonville and C College, Cambridge, and Prof. T. R. Elliott, Dire of the Medical Unit, University College Hospi London, have been appointed members of the Med Research Council to fill the vacancies caused by retirement of Sir Frederick Andrewes and Sir Cuth Wallace.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCXXXV.—THE TREATMENT OF DIPHTHERIA.

EVEN after our 30 years' experience in the treatment of diphtheria by antitoxin it still seems essential to insist on the necessity for immediate treatment. The chances of recovery diminish steadily with the lapse of time between the onset of the disease and the administration of serum, and valuable hours may be lost in waiting for a bacteriologist's report. Generally speaking if a case is suspicious enough to be swabbed it is suspicious enough to be given a dose of antitoxin, and it is even sound practice to give antitoxin in the face of a negative culture where the clinical appearance suggests diphtheria. The only objection to antitoxin is the occasional occurrence of serum sickness, and if a concentrated serum is used this risk is greatly reduced. The belief that diphtheria antitoxin plays a part in the production of the paralytic sequelæ of the disease is without foundation, whilst the occurrence of "antitoxin" abscesses merely indicates faulty technique in the injection.

Isolation.—A patient treated at home should be isolated in a well-ventilated room, and the services of a trained fever nurse engaged. Small pieces of clean rag should be provided for wiping up discharges and these should be promptly burnt after use. The patient's crockery and spoons should be specially marked and boiled after each meal. Isolation may be terminated when two or three consecutive negative cultures obtained at a few days' interval have been reported. Before returning the room to its normal use it should be very thoroughly "spring" cleaned and the patient's personal linen and bedding disinfected by steam. Toys and books should be burnt.

Serum Dosage.

On this point there are two principal schools of thought, one believing in the exhibition of massive doses up to 150,000 or more units of antitoxin, whilst others who find wide support in this country and the United States hold that amounts up to 50,000 units are sufficient to bring about all the benefits to be expected from serum. The following system of dosage is based on the practice of the latter school.

In estimating the dose the factors to be taken into account are the day of disease, the extent and severity of the local lesion, and the amount of toxæmia as indicated by pallor, prostration, cervical adenopathy, and albuminuria. Age or body-weight need not be specially considered since any modification that one would be inclined to make for a small child is counter-balanced by the greater susceptibility at that age. Mild cases seen early with slight patching on one or both tonsils should be given from 2000 to 6000 units of antitoxin. Cases presenting a moderate amount of toxæmia and patching on both tonsils will require from 10,000 to 16,000 units of antitoxin. Severe cases with extensive membrane involving the fauces, uvula, soft palate, and posterior pharyngeal wall, accompanied by profuse nasal discharge, fœtor and profound toxæmia should be given 30,000 or 40,000 units at once. These doses apply to cases coming under treatment on the second or third day; cases presenting corresponding lesions after this period require an additional 2000 to 10,000 units according to their severity. In the mild and moderate types an increase of dosage is indicated if a nasal discharge is present, or if the faucial pillars, posterior pharyngeal wall, or uvula are involved.

The ideal method is to give an adequate single dose at the outset of the treatment, but even the most experienced do not always find this possible, and the throat and general condition should be carefully re-examined at the end of 12 or 24 hours; a spread of the membrane, or the failure of a nasal discharge to clear up indicate repetition of the dose.

The serum may be injected subcutaneously, intramuscularly, or intravenously, the route now most extensively employed being the intramuscular, and the site the middle of the outer aspect of the thigh. In severe or late cases intravenous injection of at least part of the dose is preferable, but in children this is frequently difficult, and it may be wise to adhere to the easier intramuscular method. Before intravenous injection the serum should be warmed by standing the phials in a vessel of warm water.

Serum Sickness.—Anaphylaxis.

After the administration of serum from 10 to 50 per cent. of patients, according to whether concentrated or unconcentrated serum is used, show one or other of the manifestations of serum sickness. The commonest, and frequently the only one of these is the appearance of a rash which comes on from about the fifth to the twelfth days after injection. It may be urticarial, erythematous, morbilliform, or scarlatiniform in appearance, the first being the most usual and is generally intensely itchy, a soothing application of calamine lotion being frequently required. Arthritis is less common and may be present with the rash or alone; pain is the outstanding feature, little or no swelling being visible. Localised œdema of the eyelids, upper lip, genitalia, or hands and feet may occur, also some degree of pyrexia.

Anaphylaxis happens so rarely that it should never be considered a contraindication to serum administration. However, persons who have been previously sensitised by injections of horse serum, or are subject to asthma, should be desensitised by injecting subcutaneously 0·5 c.cm. of serum and following that up in not less than four hours with the therapeutic dose. If a patient has to receive antitoxin more than ten days after a previous injection the same procedure should be followed.

General Management.

Until all danger from circulatory failure is past, the patient should be rigorously prohibited from sitting up in bed, only one soft pillow being allowed at first, and every possible strain being avoided. The bowels should be kept open by enemata. The diet should be fluid at first, but liberal when the febrile period is over. In moderate cases after two or three weeks a second pillow may usually be given, then a third, then sitting up may be permitted, until finally the patient is allowed up. In severe cases, however, or in those whose pulse is unsatisfactory, these advances require to be made with more caution, the patient being confined to bed for six to eight weeks. After further medical supervision is unnecessary a month's holiday is desirable. Patients who have suffered from circulatory disturbances should avoid hard exercise for a year or more.

Local treatment of the membranous deposit is superfluous except in severe cases or where there is superadded secondary infection, when gentle douching with warm water may be carried out.

Heart Failure.

The patient should be placed in a completely recumbent position on the appearance of pulse irregularities in rhythm or rate. If there is pallor or faintness the foot of the bed should be raised on blocks, and fluid nourishment given frequently in small amounts; hypodermic injections of strychnine or camphor in oil may be called for. Adrenalin has gained some reputation in this condition; its value or indeed that of any drug, is problematical, but they should always be tried. In sudden collapse, or when vomiting comes on, all feeding by the mouth should be stopped and rectal salines given, as well as hypodermic stimulation every two or three hours. If pain is present, hot fomentations should be applied to chest and abdomen. In extreme cases, when restlessness is a feature, a carefully estimated injection of morphine may give the patient a spell of quietness, and postpone the almost inevitably fatal issue. Thirst, often a distressing feature when fluids by the mouth are cut off, may be partly alleviated by rectal salines when these are retained; the lips and mouth should be moistened frequently with iced or acidulated water.

Post-diphtheritic Pareses.

These tend to spontaneous recovery. The patient must be kept at complete rest and strychnine given by the mouth. The tendency to nasal regurgitation

in palatal paresis can usually be overcome by careful feeding with semi-solids. In pharyngeal paresis the patient requires to be fed by the nasal tube and the foot of the bed raised so that saliva may drain from the mouth. The recovering patient should be carefully fed at first with thickened fluids.

Laryngeal Diphtheria.

Laryngeal diphtheria should be treated by an immediate dose of antitoxin of 12,000 to 20,000 units; if severe faucial or nasopharyngeal lesions are present in addition 30,000 to 40,000 units should be given. A croup kettle and a half-tent should be arranged so that the air in the neighbourhood of the head is kept moist and warm by a current of steam. Hot fomentations should be applied to the neck frequently. In hospital it is usual to postpone interference as long as possible, but in general practice this may be dangerous. Rapidly recurring spasms of dyspnœa, great restlessness, cyanosis, and a fast flickering pulse are obvious indications, but there are many lesser gradations of the obstructive syndrome whose gravity has to be estimated. It is better to operate early than too late, and when the doctor cannot be within easy call it is sound practice to operate.

Tracheotomy.—Intubation is essentially a hospital procedure, and the operation to be recommended for the practitioner is high tracheotomy. A detailed account of this is not possible here, but some of the important points may be stressed.

An anæsthetic is not necessary, but the patient must be firmly held, especially the head, which must not be allowed to move from the vertical. The anatomical landmarks must be carefully selected, the midpoint of the lower border of the cricoid never being lost sight of. The incision should be *absolutely* in the midline. Bleeding need not cause alarm, and steady swabbing must be carried on to prevent the field of operation from being obscured. When the trachea is opened there is no urgency about inserting the tube until the first spasm of coughing has cleared away mucus, blood, and fragments of membrane. In the after-treatment the main consideration is to get the tube out, and attempts to this end should be made about the third day after operation. As a rule the patient can be fed quite well by means of a feeder or a spoon and very rarely is the nasal tube required.

Diphtheria in other Situations.

Nasal diphtheria with membrane formation requires from 6000 to 8000 units of antitoxin, and cases in which there is a watery or blood-stained nasal discharge containing *B. diphtheriæ* will usually yield to a small dose of 2000 units. Conjunctival diphtheria should be treated with 6000 or 8000 units, and in diphtheria complicating operation wounds or occurring as a secondary infection of skin eruptions it may be necessary to give large initial doses up to 20,000 or 30,000 units.

Prophylaxis.

Passive immunisation can be conferred by the subcutaneous injection of 500 units of antitoxin. The protection lasts about three weeks and is immediate.

Active immunisation can generally be secured by three doses each of 1 c.cm. of toxin-antitoxin mixture subcutaneously. The procedure should be delayed till after the ninth month of life; in children under school age no preliminary Schick test is necessary. Up to puberty a preliminary Schick test without a control should be performed, but after that age, and in retesting after immunisation, all tests should be controlled by the heated inactivated toxin. Protection takes some months to develop; the lapse of six or twelve months will be found a convenient interval before retesting. Those still susceptible as revealed by the Schick test should receive a further course of toxin-antitoxin injections.

Carriers.

Local applications have little effect, and the best prospect of terminating the carrier state is held out by investigating the nasopharynx and correcting any deformity or pathological condition. Tonsillectomy and removal of adenoids are often useful.

ALEX. JOE, D.S.C., M.D. Edin.,
Medical Superintendent, North-Western Hospital (M.A.B.).

Special Articles.

A FURTHER VISIT TO GERMAN SPAS

A VISIT to some of the West German spas w reported in THE LANCET of June 12th, 1926. Th spring an opportunity was given to our representati to visit nine other spas, and so to complete his accou of German inland watering places.

AACHEN.

Aix-la-Chapelle, to use the more familiar nam is situated on the main line from Brussels to Cologn just on the German side of the frontier betwe Belgium and German. It is an industrial town 150,000 inhabitants, chiefly engaged in maki needles and in the woollen industry. At its weste end is the spa, at the foot of well-wooded hills, a as the prevailing winds are from the west the smo from the town and its factories rarely approach the area occupied by the Kurhaus with its baths a wells. Indeed, unless one climbs the wooded slop which overlook the town, the neighbourhood of t industrial area is forgotten. The hot sulph springs issue at temperatures varying from 162° downwards; the hottest, of course, being cool before use. In addition to sulphuretted hydrog the waters contain sodium chloride, sodium bic bonate, and sodium sulphate, being thus well suit for the treatment of rheumatism and gout. He is found an excellent form of douche massage pecul to the place. The patient enters a deep immersi bath, with steps on either side, in company with t bath attendant. The latter, seated facing the patie applies massage and under-current douching for so 15 minutes, during which the bath is gradua emptied. The manipulations over, the attend leaves the bath, which is gradually refilled, and t patient lies quietly in the warm water for the p scribed period. He is then dried with warm tow and sent to rest, or, if he be physically fit, is allow to swim or wallow in a commodious bath of runni warm sulphur water.

Until the introduction of intravenous metho Aix-la-Chapelle was justly famed for the treatment f syphilis and parasyphilitic ailments by the combi use of mercury inunction and sulphur waters. certain number of these patients are still treated he but most of those coming for the cure are suffer from rheumatism, gout, skin diseases, torpid liv or intestinal catarrh. The principal hotel adjoin the baths and Kurhaus is well warmed and m comfortable in every way. Mention should made of the Landesbad, a hospital of 365 beds, the treatment of the insured classes, with well-staf laboratories for all pathological and biochem investigations.

KREUZNACH.

This spa lies in the valley of the River Nahe quarter of an hour's journey from Bingen, where Nahe flows into the Rhine. Here are large saltwo and radio-active brine baths containing lith and iodine are the most important features of treatment. The strength of the baths is varied the addition of mother-lye from the saltworks o concentrated radium emanation water. Disease women, rheumatism, and "scrofula" are said to de special benefit. Scrofula would appear to be a tuberculous condition in children characterised glandular enlargement. There are several l children's homes, both for treatment and conva cence, but although several homes were visite typical case of scrofula could not be demonstra The children appeared well-fed and happy, and bracing climate and good feeding should do m to reinforce the action of the local radium emana in overcoming the after-effects of malnutrition early childhood from which many German chil suffered during the war and the subsequent infla

period. The Kurhaus and Palast Hotel was the headquarters of the German General Staff in 1917 and 1918. The baths contain inhalation rooms filled with vapourised saline water for the treatment of catarrh of the lungs, nose, and throat, and it was of passing interest to be told that in this foggy atmosphere the ex-Kaiser sought relief. The Palast Hotel has once more assumed its normal function, and is a most comfortable place. The hotel adjoining is still the headquarters of the French occupying this area. Kreuznach has some 27,000 inhabitants, and is the centre of the Nahe wine industry.

BAD MÜNSTER AM STEIN.

This lies in the Nahe valley, a few miles above Kreuznach, in the concavity formed by a wide bend in the river, on the opposite bank of which the Rheingrafenstein rises sheer to a height of 300 metres. The waters are radio-active salines, and the bath-houses, when rebuilt in 1911, were so constructed as to retain as much as possible of the natural radium emanation. The lawns in front of the Kurhaus are bounded on two sides by high Gradier-Werke, being stacks of brushwood used for concentrating the salines by evaporation. Consequently, the patients spend a large part of their time in an atmosphere impregnated with moisture and salt, and even in the height of the summer the gardens are cool and pleasant. Bad Münster is little more than a large village, but it has modern sanitation and lighting, and is a real beauty spot. Shaded walks in the valleys or stiff climbs in the hills afford choice in plenty. The diseases mainly treated are gout, rheumatism, scrofula, and female ailments.

BAD MERGENTHEIM.

Mergentheim, on the River Tauber, is the old Frankish town whose castle was for centuries the home of the powerful "Deutsch-ritter," a religious order of German knights. The old castle and town are separated by a park and the river from the Kurhaus and modern buildings surrounding the springs. Unlike most German spas, Bad Mergentheim is privately owned. It is to be hoped it will weather the lean years, for in many respects Mergentheim is an ideal cure place. Although patients may live in the lodgings or hostelries in the old town, the principal hotels belong to the spa, and each hotel has a resident doctor. In all these hotels different kinds of diet are prepared daily, and each kind of diet is subdivided according to the needs of the individual patient, the quantity as well as the quality being ordered by the medical resident. A shady promenade and colonnade adjoins the springs, and by the time the orchestra arrives to play the opening morning hymn, most of the patients are on parade sipping their mineral waters. More importance is attached to drinking the waters than in most spas. They are bitter salines containing different quantities of sodium and magnesium sulphates as well as sodium chloride. The ailments principally treated are cholecystitis and gall-stones, cirrhosis of the liver, obesity, diabetes, and catarrhal diseases of the stomach and intestines. At Bad Mergentheim the cure is of primary importance, but full provision is made for amusement, and with Würzburg and Rothenburg within easy reach, it is a very pleasant spot to visit.

BADEN-BADEN.

In a pamphlet issued by the municipal inquiry office it is stated, "Only a small percentage of those who visit Baden come for the cure." More's the pity, but the reason is not far to seek. Baden has been made so attractive by nature and art that it can rely on drawing a sufficient number of visitors whose spending power renders the authorities more or less independent of the invalids on whose support other spas must rely. Gardens, reminding one of the ordered beauty of the Cambridge "Backs," border the banks of the rippling Oos in the bottom of the valley, surrounded by the mountains of the Black Forest. In the spring, with magnolia, syringa, azalea, chestnut, and lilac in bloom, with a soft, warm air sufficiently stirred by the cool breezes following the course of the river, the outdoor conditions are ideal for the invalid or the weary.

The spa waters issue at a temperature of 154° F., and contain lithium and iodine. The bathing establishments have evolved an elaborate form of treatment whereby the patient enters in turn a hot air room, very hot air room, douche massage, steam room, hot swimming bath, cooler immersion bath with sand at the bottom, still cooler swimming bath, cold douche room, and finally a cold plunge bath. This takes about 1½ to 1¾ hours. It is all quite pleasant, and the patient is ready for his couch and towels when it is over. Subsequently a feeling of buoyancy and hunger follows. This must be the moment of temptation for the obese gentlemen who appear to form the majority of those undergoing the cure. The gouty and rheumatic take this treatment, and there are well-equipped inhalation rooms for those suffering from bronchial catarrh. There are luxurious hotels where wealthy people can enjoy rich food and dance till the small hours. It is evident that the practice of early water drinking is not as prevalent as it once was.

BÜHLERHÖHE SANATORIUM, some 800 metres above sea-level, is reached by a 40-minutes irregular ascent from Baden-Baden through the Black Forest. Originally built to accommodate 12 German generals in need of rest or convalescence, it is now under private control, and offers rest and open-air treatment in most attractive surroundings. Diet receives careful attention, and there is a small hydropathic department. The resident physicians have a laboratory where necessary pathological and biochemical investigations can be carried out. Bühlerhöhe is specially recommended for the after-cure of patients with heart disease who have been treated at Nauheim and Kissingen, or after sulphur treatment at Schinznach. Anæmia and non-infectious diseases of the respiratory system are also treated.

WILDBAD.

The little town is situated at a railhead 12 miles up a valley from the main line from Paris to Vienna. That is has historic associations, readers of "Jew Süss" will remember well—they would also understand the presence of several royal baths in the comparatively small bathing establishment. The spa waters issue at a temperature of 91° to 104° F., and are consequently applied without previous heating or cooling. They contain little mineral matter, but are radio-active. Drinking the waters is not pressed, though there is the usual Trinkhalle. Rheumatism and gout are treated by immersion baths, and the waters frequently cause a "bath reaction" after the first five or six baths, after which more rapid progress may be expected. Dr. Schober has made some experiments indicating that the local radio-active waters stimulate a more rapid growth of protoplasm than plain water. Through the valley of Wildbad runs a trout stream, and visitors for the cure can obtain permission to fish a long stretch of likely-looking water.

BAD REICHENHALL.

Reichenhall is a country town, 1500 feet above North Sea level, surrounded by the snow-capped peaks of the Bavarian Alps. The frontier between Austria and Germany runs between Reichenhall and Salzburg, which is only a few miles away, but the passport visa is obtained without difficulty to enable visitors to see the historic palaces and castles of Salzburg. There is a daily air service to Reichenhall from Munich, and as the aeroplane reaches Reichenhall early in the morning and does not leave till evening, it is available for short or long flights over the Bavarian Alps and Austrian Tyrol. Reichenhall has some of the richest salt springs in Germany, containing 24 per cent. salt (as compared with the 2–4 per cent. of sea water) and whilst winning salt is the main industry of the 7000 inhabitants, these salines, containing bromine and iodine salts, are carefully graded for bathing purposes. The mountain air, mild and clear from impurities, is specially suitable

for the sufferers from non-tuberculous pharyngitis, laryngitis, bronchitis, asthma, and hay fever, who flock here from all parts of Germany and Austria. The climate is also beneficial in rickets and scrofula. Inhalatoria and compression chambers abound, whilst the notice that smoking is forbidden meets the eye everywhere. Spitting on the ground would probably be followed by banishment. There is a peasant theatre where the players wear the picturesque national costume. The artists are of peasant origin, but are true professionals. Each performance ends with the folk dances of the Bavarian Highlands, which are invigorating to watch, and recall the small hours of a St. Andrew's night. Bavarian hospitality must be experienced to be appreciated; both place and people make the visitor feel at home.

BAD ELSTER.

This Saxon spa is only a few miles from the neighbouring Czecho-Slovakian spas, Franzensbad and Marienbad, and has very similar waters. These all contain iron and varying quantities of Glauber's salt and sodium bicarbonate, with free carbonic acid gas. Peat baths and packs are used on a large scale. The chief indications for the cure are anæmia and disorders of the respiratory system—tuberculosis excluded—cholecystitis and gastric catarrh, diseases of women, particularly inflammatory conditions of the pelvis and menstrual disorders. The last wing of the new bath-houses has just been opened, and is spacious and well-equipped. Outdoor treatment in sunlight and swimming baths has been well-developed, the climate and surroundings being particularly suitable. Bad Elster is only a small place, but has an attractive casino and theatre and pleasant countryside.

Dr. Köhler's sanatorium is a well-equipped private institution for diagnosis and treatment, where diet is properly controlled. Attached to it is a home for the open-air treatment of poor children suffering from surgical tuberculosis and malnutrition. Excellent work is being done here. Dr. Köhler said that at one time he was only enabled to keep the place going by the aid of money received from the British "Save the Children" Fund. The money sent to him was well spent.

BAD BRAMBACH.

Brambach lies on the frontier between Saxony and Czecho-Slovakia, being about half-way between Bad Elster and Franzensbad. It was only in 1910 that building operations revealed what proved to be the strongest known radio-active springs. There is a large mineral water factory and bottling department, which exports a palatable table-water and ginger ale, the only other buildings being the four small hotels owned by the same company. The bathing rooms are in these hotels. The climate is bracing, and the atmosphere has been shown to be radio-active up to a good height and over a considerable area around the springs. Bad Brambach is still a spa in embryo, but has waters which may some day make it famous.

SOUTH AFRICA.

(FROM OUR OWN CORRESPONDENT.)

Report of the Hospital Survey Committee.

A REPORT by this Committee on the hospital facilities and kindred services in the Union was presented to both the Houses of Parliament on June 25th. Sir Edward Thornton was chairman of the Committee, of which there were four other members, and in addition a member for each of the four provinces was nominated to take part in the investigation in so far as the particular province was concerned. The needs of each of the four provinces are dealt with separately in detail. The report lays stress on the extreme shortage of beds at most of the public hospitals, particularly in regard to provision for the coloured and native races. The overcrowded state of many of the hospitals has already been pointed out b the Hospital Committee of Inquiry in 1925, and th present Committee is satisfied that the strain on th hospital beds of the Union to-day is appreciably wors than it was in 1925; at hardly any large centre, wit the exception perhaps of Johannesburg, can it recor any amelioration of conditions. Greater hospita accommodation is required in the Union than i European countries, as separate provision has to b made for European, coloured and native patient The Committee concludes that in other countries ratio of one bed for every 200 persons is the ideal t be aimed at, and that in practice a community is no ill-served if it has one hospital bed for every 250 o its population. In most countries it is generally foun that proportionately greater hospital facilities ar required by the inhabitants of a densely settled are than by those living in the more sparsely populated This is true to a certain extent for South Africa, bu here there are other factors to be taken into co sideration, such as the proportions of the constituen elements of the population and the character, habit and development of each section thereof. Thus it wi be many years before the raw native living in th heart of Natal or the Transkei will require the sam proportion of hospital bed accommodation as th European. Even among Europeans the demand vari enormously. The older generation of Boers, particu larly amongst the farming community, has not lo its fear of hospitals, and in an area such as the Oran Free State the demand for accommodation Europeans is relatively small.

Among the constructive proposals made in th report is the suggestion that each province shall b divided for hospital purposes into a number of centr areas. Under this scheme the Province of the Cape Good Hope would be divided into six of these area and the Transvaal, Natal, and Orange Free State wou each be divided into two. The Committee estimat that if its proposals are accepted a capital expenditu of over £2,000,000 on hospitals will have to provided for the provinces over a period of four or fi years. The approximate figures for each provin are: Cape of Good Hope (including £90,000 for chron sick), £950,000; Transvaal, £574,000; Orange Fr State, £400,000; and Natal, £235,000. The estimates include the cost of building a new gener hospital at Cape Town, the new hospital at Pretor and the new hospital at Bloemfontein; to the co struction of which, it is understood, the Governme is already committed in principle. Their erection w cost not less than £1,000,000. The Committee regar its proposals as minimal. Their adoption would n entirely solve the very unsatisfactory problem of t hospital service in the Union, which in three provinc particularly has been sadly neglected, but it wou at any rate, simplify the position of the Government it ultimately takes over the control of the hospita The Committee believes that Government control bound to come in view of the increasing body of pub opinion which is in favour of it.

Native Medical Practitioners.

In order to bring European medicine within rea of the native population it has been suggested th facilities for the training of natives as medical pra titioners are required. A committee appointed so months ago to consider this question has expressed t conviction that the needs of the native reserves a locations will not be met by providing for an influx natives into the medical profession. Experience other parts of Africa shows that it is exceptional f a native medical practitioner to be content to pract in his home surroundings. He nearly always drifts in a large town, and money spent on his education w the object of providing medical attention for l people in the bush is to a large extent wasted. It h been found impossible in practice to draft agreemen that will bind such practitioners. Apart, howev from this consideration the committee thinks that will not be practicable for many years to give nat students facilities for full medical training in t

outh African hospitals. It will even be a long time robably before native nurses can safely be given sters' posts in the native wards of our large public ospitals, for native nurses in South Africa as well as sewhere in the continent have been found lacking initiative, and tend to become slack when not under ose supervision.

Much to the disappointment of the profession the ledical, Dental, and Pharmacy Bill has been dropped r this session. This is due almost entirely to the mount of time taken up in the Assembly by discussion f the Flag Bill.

During the last few days of the Parliamentary ession the Public Health Act Amendment Bill was assed in a truncated form—i.e., the more urgent lauses dealing with the more efficient administration f public health affairs on the alluvial diamond fields ere passed, while the controversial clauses covering accination, hospital administration, and other matters ere dropped.

The Administrator of the Cape has promised the ppointment of two additional school medical inspectors r the Province, which will make four in all. There as been a great need for a long time for an increase staff in this department.

In Cape Province a native woman recently gave rth to four sons and died in giving birth to a fifth. wo of the quintuplets survived.

The last few years have seen an alarming increase the numbers of wild rodents in many areas. This is tributed partly to the extermination of the natural emies of the rodents—i.e., the smaller cats, owls, and ongooses. The cats were destroyed for their skins. he greater ploughing of land and cultivation for ain and sweet grass make it easier for rodents to rrow and multiply.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Definition of Patent Medicines.

HUNGARIAN law distinguishes between medicines ncocted or mixed by pharmacists, specialties made pharmaceutical manufacturers and sold only by e pharmacists, and patent medicines of the kind lled in England secret remedies. In Hungary there a turnover tax which is payable on medicaments. ne tax is lowest, of course, on regular pharmautical preparations, and highest on the patent edicines, and in order to determine which specialty a regular medicine and which a patent medicine, has been necessary to lay down some definitions. ne regulation states that by the term "patent edicine" (secret remedy) are to be understood such aterials or preparations as are alleged to avert, re, or mitigate any disease, suffering, deficiency, or orbid condition, or to increase or decrease certain odily capabilities whenever (1) their composition, ualitatively or quantitatively, is kept a secret from e buyer; (2) their regular use might be detrimental health or deters the user from employing actually luable medicines or availing himself of efficacious edical help; (3) their selling price is disproporonate to their value; or (4) their advertisement is ot to cause misunderstanding.

Drug Addiction.

A committee on the control of drugs has been ppointed by the Ministry of Health in order to cide how far physicians are justified in prescribing ugs such as heroin and morphine for drug addicts. ne appointment of the committee is the outcome of ntinuous requests for guidance received from ysicians in all parts of the country. Numerous ses have come to the knowledge of the authorities which drug addicts have constantly obtained pplies of morphine, heroin, and other drugs on octors' prescriptions. It is alleged that in some instances these prescriptions are given so that the drug victim may satisfy his cravings, and it is suggested that penalties be inflicted in such cases. For this new legislation may be necessary, but it is believed that the evil can be remedied by the issue of an authoritative statement, the question of penalties being left for the present in the hands of the medical associations.

A Case of Aspirin Poisoning.

Toxic symptoms following the use of the different preparations of acetosalicylic acid have often been reported, but a case recently encountered in a country town in Hungary has a special interest. Fifteen minutes after the ingestion of 1·0 g. aspirin, bought from a regular chemist, the patient developed swelling of the upper lip and deglutition became painful, whilst the pulse- and respiration-rates were much increased. The swelling soon extended to the entire head and was not relieved by cold applications, and somewhat later generalised urticaria made its appearance. On the following day the symptoms disappeared. It is suggested that the symptoms were due to carbolic acid poisoning resulting from the drug being split up in the stomach; the urine is said to have contained large amounts of this acid.

Excessive Heat in Hungary.

The summer heat this year has been considerable, the midday temperature being as much as 35° C. (95° F.) in the shade, the highest figure of recent years. Besides the ordinary inconvenience of hot weather, there are those arising from scarcity of water, particularly in provincial places where the supply is derived from wells. Rivers are almost dried up, and if the drought continues pollution of the remaining water and consequent spread of typhoid and dysentery are to be feared.

X Rays in Ophthalmology.

At a recent meeting of the Hungarian Ophthalmological Society Dr. Béla Horváth read a paper on his experiments on the treatment of certain eye diseases with X rays. He started his experiments two and a half years ago, and has treated 168 patients, the rays being applied on 288 occasions. The dose never exceeded one-third of an erythema dose, and no harmful action was observed. The patients thus treated suffered from many kinds of ocular diseases, including tuberculous conjunctivitis, trachoma, keratitis, chorioretinitis, scleritis, and iritis. As regards the results achieved, a considerable effect was noticed in tuberculous conjunctivitis with the formation of phlyctenules, although the effect on the subjective symptoms and the keratitis was even more pronounced. In trachoma both corneal ulcers and pannus receded quickly; in postoperative hæmorrhages the visual power improved to 5/15 within a few days, whilst in three cases of chorioretinitis the sight improved considerably. In fistulous or phlegmonous dacryocystitis and lymphatic keratoconjunctivitis the effect was variable. In ten cases of parenchymatous keratitis the cornea cleared up rapidly. Dr. Horváth also treated 62 patients suffering from iritis, the result being most striking in acute cases. Local treatment was, of course, employed as well. In a case of relapsing uveal hæmorrhage rapid improvement was noted.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The General Prisons Board.

THE General Prisons Board of Ireland, and in recent years of the Irish Free State, consisted of three members, one of whom was always a medical man. For the past 15 years or so the medical member also acted as inspector of reformatories and industrial schools. A vacancy had recently occurred on the Board by the retirement of Dr. C. J. McCormick, and the Government has decided not to fill it. Instead of

appointing a medical member it is intended to have inspection of the prisons carried out by a medical inspector of the Department of Local Government and Public Health, and this decision has elicited protests from several medical bodies. It is pointed out that inspection of the prisons was by no means the only duty of the medical member of the Board. Being charged with equal responsibility with his colleagues in all matters of prison administration, he was in a position to make his wishes effective. A medical inspector who is in a subordinate position has no further responsibility once he has submitted a report, and he has no power to ensure that his advice is followed. It is suggested, indeed, that instead of medical influence in prison administration being diminished, it ought rather to be increased and that the study of criminology from a scientific point of view should be encouraged.

MEDICINE AND THE LAW.

Marriage of Blood Relations.

THERE must be some eugenic principle in the mind of a man who seeks to prevent his descendants from marrying blood relations. But, if he tries to enforce his wishes by imposing conditions in his will, he must be careful to frame them in such a way that the law courts will support him. A testator left residuary estate to his son for life and after the son's death to the son's children "provided he does not marry a relation by blood, as I wish to mark my great objection to marriage between blood relations." The son, a bachelor aged 37, took the opinion of the Court of Chancery as to whether he would lose his life interest if he knowingly or unknowingly married a blood relation, and whether the limitation upon his choice of a bride had any legal validity. The court had no difficulty in answering that the son's life interest was safe in any event, but it found the second question more puzzling. Blood relationship could not refer merely to the statutory next-of-kin but must describe the relationship existing between any two or more persons who stood in lawful descent from a common ancestor. The chain of descent might be broken by illegitimacy, but, subject to that qualification, all persons descended from a common ancester were blood relations, however many centuries ago the common ancestor might have lived. The restriction in the will was such that it would be difficult, perhaps impossible, to ascertain definitely that any particular woman was not a blood relation. The son would know when he was marrying a blood relation; he would never be certain he was not doing so. A provision which produced these results was one likely to lead to a restraint upon marriage. Public policy requires that there should be no prohibition on marriage. On this ground the judge pronounced the condition in the will to be void. The law reports contain decisions whereby conditions imposing a partial restraint upon marriage have been held to be perfectly valid. A condition against marriage with any person born in Scotland or of Scottish parents has been upheld as valid. So also has a clause which provided for forfeiture in the event of marriage with a person who did not profess the Jewish faith or was not born a Jew. These cases may seem tainted with unreasonable prejudice, but the judges have declined to interfere as the restraint is only partial. The prospective bridegroom is still left a large field of choice in the female world. A condition against marrying a blood relation is regarded as rather more than a mere partial restraint. It is unreasonable because it is so comprehensive and so uncertain; it might tend to deter a man from marrying at all.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.—As a result of the sessional examinations of the Division of Tropical Medicine and Hygiene, Dr. R. Aird has been awarded the Duncan medal.

The Services.

ROYAL ARMY MEDICAL CORPS.

Capt. F. C. Tibbs to be Maj.

The undermentioned Capts. to be Majs. (Prov.): F. R. H Mollan, G. O. F. Alley, A. J. Beveridge, and D. Fettes.

Majs. R. E. Todd, D. B. McGrigor, F. T. Dowling (grante the rank of Lt.-Col.), and J. F. Grant retire on retd. pay.

TERRITORIAL ARMY.

Lt.-Col. G. H. L. Hammerton (Supern.) is retd. on reduc tion of estabt. and retains his rank with permission to wea the prescribed uniform.

Lt.-Col. W. Lister to be Bt. Col.

Lt. E. G. Oastler, from the Supern. List for service wit O.T.C., to be Lt.

N. R. Rawson, late Temp. Capt. R.A.M.C., to be Lt.

H. S. Davies to be Lt.

ROYAL AIR FORCE.

Flying Officer G. A. Ballantyne, D.F.C., is promoted the rank of Flight Lieutenant (Dental) on promotion Captain in the Army Dental Corps.

Flight Lt. J. J. Walsh is transferred to the Reserv Class D.1.

INDIAN MEDICAL SERVICES.

Lt.-Col. W. S. Willmore to be Col.

Temp. Capt. A. H. Ernst relinquishes his temp. commn.

Lt.-Col. L. P. Stephens retires.

Lt.-Col. T. E. Fielding to be officiating A.D.M.S., Poo District, Secunderabad, vice Col. H. Boulton, on leav Maj. M. J. Williams to be D.A.D.M.S., Peshawar Distric vice Maj. B. Johnson, vacated. Maj. E. B. Wade to officiating D.A.D. of Hygiene, Lucknow and Presiden and Assam Districts, vice Maj. E. G. S. Cane, grant leave. Capt. H. T. Findlay to be Officer in Charge, Briga Laboratory, Ambala, vice Maj. R. Davidson, vacate Lt.-Col. D. O. Hyde to be officiating A.D.M.S., Burr District, vice Col. V. J. Crawford, on leave. Maj. E. Kirwan to be Superintendent, Campbell Medical School a Hospital, vice Lt.-Col. W. Harnett. Col. J. Norman Walk Surgeon to the Viceroy, to be Inspector-General of Ci Hospitals, Central Provinces, vice Col. K. V. Kukda Lt.-Col. S. G. S. Haughton to be officiating A.D.M. Kahat District, vice Col. W. O'S. Murphy, on leave. Lt.-C Wingate to be officiating A.D.M.S., Rawalpindi Distri vice Col. A. Choppling, on leave. Maj. M. L. C. Irvi specialist in medicine, C.P. District, has been appointed Kamptee and Jubbulpore for temporary duty. M MacGregor to be Agency Surgeon, Bushire, vice Maj. M. Nicholson, on leave. Capt. N. R. Obhaya, Assistant Direct of Public Health, to hold full charge, vice Dr. K. T. Mathe on leave. Lt.-Col. A. S. Leslie to act as First Physici General Hospital, and Professor of Medicine, Medi College, Madras. Maj. N. M. Mehta to act as Civil Surge Coonoor, vice Lt.-Col. A. S. Leslie, transferred. Dr. Mat Dass to be officiating Civil Surgeon, Jullandar, vice Lt.-C Kanwar Shamshere Singh, on leave. Dr. Tej Chan Pramanic, officiating civil surgeon, Shahabad to Puru to act as Civil Surgeon, Manbhum, vice Dr. B. P. Varm on leave. Dr. Baini Prashas to officiate as Direct Zoological Survey, Central Provinces, vice Maj. Seymo on leave. Dr. Mehdi Khan, medical officer in immedi charge, Sadr Hospital, Hamirpur, to officiate as C Surgeon, vice Khan Sahib Dr. Muhammad Ismail Khan, leave. Dr. Ram Sarup Gupta, medical officer in immedi charge, Prince of Wales Hospital, Cawnpore, to officiate Civil Surgeon, Cawnpore, vice Lt.-Col. H. Ross, on lea Dr. Lachmi Narayan, medical officer in immediate char Sadr Dispensary, Ghazipur, to officiate as Civil Surge Ghazipur, vice Dr. Balahadra Singh. Dr. M. Noronha to Honorary President Magistrate, Bombay.

NORTH PERSIAN FORCES MEMORIAL MEDAL.

Dr. A. Neave Kingsbury, Colonial Medical Services, been awarded the North Persian Forces Memorial Me for the year 1926 for his paper, Some Investigations Malarial Fevers, published in the Transactions of the Ro Society of Tropical Medicine and Hygiene (vol. x No. 8, February, 1926, pp. 459–481). This medal awarded annually for the best paper on tropical medicine hygiene published in any journal during the preced 12 months by any medical officer, of under 12 years' serv of the Royal Navy, Royal Army Medical Corps, Ro Air Force, Indian Medical Service, or of the Colonial Med Service, provided the Memorial Committee consider t any of the papers published has attained a standard merit justifying an award.

Obituary.

HORATIO BRYAN DONKIN, M.D. OXF., F.R.C.P. LOND.,

CONSULTING PHYSICIAN, WESTMINSTER HOSPITAL.

WE deeply regret to record the death of Sir Bryan onkin, the well-known physician and criminologist, hich occurred at his house in Hyde Park-street, ondon, on ly 26th, n the ghty-third ar of his e.

Bryan onkin was e son of civil engi- er of the me name nd the andson of ryan onkin, gineer, tronomer, nd in- ntor, who signed, mong ny other tivities, e first per-mills. was born Black- ath in 45 and eived his ly educa- on at ackheath oprietary hool, ence he nt to een's Col- e, Oxford, an open olar, to duate in e first- ss of the assical os. The owledge "the maner ters," ough er ob- ded by m, in- med his ught and writings ughout life, and to the same intensive study may be ributed the close and often destructive logic of his uments.

SIR BRYAN DONKIN.

His first intention was to go to the Bar, but he ered it in favour of medicine and took his medical cation at St. Thomas's Hospital, where he served house physician; he graduated M.B. in 1873, oming M.R.C.P. Lond. in the following year, en he was elected assistant physician to the stminster Hospital. By many generations of stminster men he will be remembered as a clear her and an excellent clinician, but his earliest cial mark in the medical profession came from his association with the East London Hospital for Children, where he had been elected physician a little previously. As the outcome of his work there he published some 35 years ago a treatise on diseases of childhood, which was based to a great extent on the records and recollections of nearly 20 years' service at the East London Hospital, and the work was recognised at once as a distinct addition to the current books on pediatrics—it was in every sense original, remarkably well written, and founded on large experience, both general and special. Later, however, his name became definitely associated with neurological investigation of a broad sort. He wrote in the medical journals and particularly in *Brain* essays that were clinically sound while philosophical in their trend, and he became known especially in connexion with criminology and psychological investigation. In 1904 he was a member of the Royal Commission appointed to consider the measures for the control of the feeble-minded, and from that time on he was a member of various departmental committees appointed by the Home Office.

From this time forward his lectures and contributions to medical and general literature were many, dealing with such allied subjects as the influence of heredity in mental disease, the part played by venereal contaminations in mental pathology, and the connexions between disease and crime, between fraud and spiritualism, and between faith and credulity. His contributions on these subjects were of the greatest value in producing logical views in many regions of thought where temptation to obscurant mysticism was being manifested. He was both in these writings and in the discussions which they would often elicit, downright in his methods, and where he was dealing

with scientific processes that are still in flux, he might give the impression of intolerance; but he was an absolutely fair man, writing as he saw, and putting out only such views as he believed himself able to justify not only out of wide reading, but especially out of ample personal experience.

Donkin was appointed a Prison Commissioner in succession to Captain W. J. Stopford on Oct. 1st, 1898, and in accordance with a recommendation of the Gladstone Committee on Prison Reform that there should always be a medical man on the Board of Prison Commissioners. He was an active member of the Royal Commission on the care and control of the feebleminded (1908), the outcome of which was the Mental Deficiency Act of 1913, which has had such beneficial effect in causing the removal of mental defectives from the unsuitable environment of prisons to certified institutions. He retired on Feb. 1st, 1910, on attaining the age of 65, but his valuable services, which were recognised by the knighthood conferred in the following year, were not lost to the Prison Commission, for he was appointed medical adviser to the Board and to be a director of convict prisons; this post entitled him to a seat on the Council of Supervision for Parkhurst Criminal Lunatic Asylum and to sign as a director certificates of insanity under the Criminal Lunatics Act, 1884. In addition he was made a member of the Board of Visitors for the State Inebriate Reformatory at Aylesbury, a member of the Visiting Committee of the Borstal Institution at Aylesbury, and a member of the Advisory Committee at Camp Hill in the Isle of Wight, a prison for men undergoing sentences of preventive detention. He was actively engaged in the duties of the last appointment until quite recently.

From "G. B. G.," of the department of the Home Office, with which Donkin was so long connected, we have received the following appreciation of a regretted colleague: "Sir Bryan Donkin's reaction on the prison staff from the date of first appointment as Commissioner was profound, and his wide general culture combined with his knowledge of general medicine, nervous diseases, and insanity increased that influence as the years went on. He was equable and kindly but firm as an administrator, and his opinions on medical subjects was universally welcomed by medical officers. He was keen to the last and it was a joy to discuss with him some point in ethics or psychology He had no use for psycho-analysis as his remarks in McBride's 'Psycho-analysts Analysed' show. The members of the Prison Service have lost a much loved friend and adviser, and the thought of one at least who stood at Sir Bryan's graveside on Friday morning last and who had known him intimately for nearly 30 years was that he had now solved the great problem on which we had had so many conversations. Sir Bryan had been obviously failing in health for the last year or so, and the Prison Service desire to tender their respectful sympathy on her loss to Lady Donkin, whose unremitting care enabled his friends to enjoy the benefit of his keen intellectual powers to the end."

Donkin's connexion with the Royal College of Physicians of London was intimate and important. He was elected F.R.C.P. in 1880, served on the Examining Board for three years, was a Councillor for the same length of time, and in 1910 was appointed Harveian Orator, when he delivered an oration on the inheritance of mental characters, showing exactly that catholic spirit in scientific inquiry for which he always stood. Harvey said: "The son is born like his parents, and virtues which ennoble and vices which degrade a race are sometimes passed on to the descendants through a long series of years." The considerateness and conciseness with which Dr. Donkin treated the vast questions arising from such a theme were recognised by all who read this Oration, in which will be found the theories of crime and the conceptions of the nature and temperament of criminals on which he relied in his various directions of public work.

Many of the special circumstances in his Government appointments, as well as the general fact of his long career as a hospital physician, conspired to giv Donkin a deep interest in syphilitic problems in thei widest sense; he approached them from the socio logical as well as the pathological side. He thu became a vigorous supporter of his conviction shared by many others, medical and lay, that medica men should make known to their patients those mean of prophylaxis against venereal infections with whic science has of late years supplied us. Consequentl when some ten years ago the association termed th National Council for Combating Venereal Disease —now the British Hygiene Social Council—wa embarrassed by strongly divided opinions on thi question, Donkin became alike the most eloquen and the most logical of those who held other views He thought that medical men were hampered i giving this information by mediæval doctrine, leadin them to regard sexual disease from a different stand point from that which they maintained toward all other diseases. He did not minimise the forc of moral or religious instruction, but, as he did no consider that these factors would operate successfull to a considerable extent in checking the gratificatio of sexual instinct by irregular intercourse, he hel that the dissemination of the venereal diseases shou be checked by the promotion of effectual prophylax for exactly the same reasons as those which wou be induced as the arguments for preventive measur in respect of other diseases.

From his life-long friend, Sir Seymour Sharkey, v have received the following tribute: "I first ma Donkin's acquaintance in 1873, when he was hou physician to Dr. Murchison at St. Thomas's Hospita and acquaintance soon ripened into friendship whi lasted as long as he lived, for Donkin was a trus friend, loyal and affectionate, whose ardour cou cool only under very exceptional circumstanc Having won an open scholarship at Oxford and lat taken a first-class in "Greats," he possessed a ve solid foundation on which to build a career, and bei a great reader and interested in most human affa he naturally became a very interesting companio He was fond of conversation and of comparing h views with those of others. He formed very defin opinions and supported them keenly, but witho dogmatism. To hear him conversing with wom which he was very fond of doing, even on diffic subjects, was a lesson in good breeding. He spo with as much care and consideration as he show to men, but treated them with infinite gentlen and so gained many a devoted friend and admir On public questions where his opinions were direc opposed to those of his friends he could carry on long debate without creating bitterness. Don was a man who had his heroes and chief amon these was the late Sir Samuel Wilks. He took leading part in the foundation of a small din club, with Wilks as its first president, which m three times a year and was called the "Fifteen Clu and after Sir Samuel Wilks's death the "Sam Wilks Fifteen Club." The members consist eminent surgeons and physicians on the staffs of great London teaching hospitals. It was foun in 1885 and is flourishing now in its forty-third y Donkin was secretary from its foundation until death. In February, 1924, on the proposal of Thomas Barlow he undertook to write a sh history of the club, a task which he accomplis in 1926."

Donkin married first Augusta, daughter of Co di Langhi, a Polish lady, and the widow of P Edward Palmer, the oriental scholar; he mar secondly, late in life, Marie, daughter of Will Reston, of North Carolina, and widow of Mr. W Bates, of Belfast. In private and in club life he a man of many friends, to whom his qualities of f and sincerity appealed. At the Savile Club he be especially missed, for he was a member of v long standing, and with many close ties to his fell members. Despite his age and the effects of a re and severe illness he maintained good health till end, the terminating phase being short.

CHARLES THEODORE WILLIAM HIRSCH, M.R.C.S. ENG.

Dr. Charles Hirsch, who died rather suddenly on ıly 28th after an operation, was 58 years of age. e was born in London, educated at King's College ıd the London Hospital Medical School, and ıalified L.S.A. in 1890, taking the conjoint qualifica- ɔn a year later. After holding a resident appoint- ent at the North-Eastern Hospital for Children and sisting in the ophthalmic clinic at the London ospital, he went out to Fiji as a medical officer ıder the Colonial Office. While there he conducted careful inquiry into a form of pernicious anæmia ry prevalent in the islands, the origin of which he tributed to the absorption of intestinal toxins acting ɔon the liver and giving rise to a condition of ıronic hæmolysis. On returning home after six ars he settled in Woolwich, where he entered into ırtnership in a general practice, was elected to the aff of the Woolwich and Plumstead Cottage Hospital, ıd became civil surgeon to the Royal Arsenal. At e same period he was divisional surgeon to the etropolitan Police, a district medical officer of the etropolitan Water Board, and a medical referee of e Royal Arsenal Coöperative Society. At this time, ɔ, he was an enthusiastic supporter of the move- ent for first-aid, and lectured for the St. John nbulance Association and at the L.C.C. evening ıools. For some years he was surgeon to the ıining ship *Warspite*.

On the outbreak of war in 1914, Dr. Hirsch held captaincy in the Home Reserve of the R.A.M.C., d became anæsthetist to the Royal Herbert ɔspital, Woolwich, and later to the Military Ortho- ɛdic Hospital at Shepherds Bush. The arduous ɔrk undermined his health and he had to undergo ɛerious abdominal operation from which he narrowly ɛaped with his life. After the war he devoted nself exclusively to anæsthetic work, and was norary officer to no less than nine hospitals— mely, the London Temperance, the Grosvenor and maritan for Women, the Metropolitan Nose, Throat d Ear, the Western Ophthalmic, the National ntal, the Maida Vale and West End for Nervous sease, and the Royal Ear. This work would have en sufficient in itself to occupy the energies of a ong and vigorous man, for he was most punctilious carrying out his duties at all of them, but in dition he was greatly in demand for private anæs- ɛtics. Outside his professional work Dr. Hirsch s a keen motorist, and was always well ormed upon the latest in technical equipment. ɛiting on motor-car matters became a hobby to n and for many years he kept readers of E LANCET in touch with them. Of his personal alities a surgeon friend writes: "Dr. Hirsch was most capable, careful, and helpful anæsthetist, npathetic to his patients and always on the alert try new methods and improve old ones. He was admirable teacher and many post-graduates have ɔse to remember with gratitude the lessons they ɛrnt from him. Nothing was too much trouble for n. At all times of day and night, whether for spital or private work, he was the same cheery ling worker."

On July 25th, after a full day of hospital work, had a recurrence of his old symptoms and died rtly after operation two days later. He leaves a low and one daughter.

HOSPITAL SUNDAY FUND.—This Fund will amount August 9th to £79,100, and the committee recommend distribution of £79,000. Grants made include: London spital, £7080; Middlesex and Convalescent Home, 75; Guy's, £3270; St. George's, £3200; St. Thomas's, 35; University College, £2465; Royal Free, £2325; yal Northern, £2150; King's College, £2080; West- ster, £1750; and Charing Cross, £1660. The report es that 7½ per cent. of the total sum available for distri- on has been appropriated to the purchase of surgical liances, and 2½ per cent. for district nursing associations.

BRITISH AND AMERICAN NEUROLOGISTS.

MEETING IN LONDON.

(*Continued from p. 259.*)

THE joint meeting of the American Neurological Association and the Section of Neurology of the Royal Society of Medicine was continued on Wednesday, July 27th, when the morning was devoted to a discussion on

THE CEREBELLUM.

Dr. H. A. RILEY (New York) presented a paper by himself and Dr. FREDERICK TILNEY (New York) on the comparative morphology of the cerebellum, first demonstrating charts and models of the inferior olive and its connexions, and particularly the lateral expansions of the cerebellum in the primate series. He had gathered as many forms as possible in the mammalian series in order to show a correlation of the arbor vitæ with the physical form of the animal concerned, and the patterns of cerebellum shown on the screen represented an evolutionary series. The following conclusions had been reached: (1) The modification of Bolk's cerebellar diagram and scheme showed a division of the anterior lobe into definite vermal and hemispheral portions. (2) The division of the cerebellum into an anterior and a posterior lobe was sufficient; no useful purpose was served by adding a middle lobe. (3) The arbor vitæ and folial patterns showed that the most cephalic and the most caudal portions of the vermis underwent the least degree of significant modification. (4) The ungulates developed a paravermis in lobule C and lobule B. (5) The aquatic mammals showed a very striking uniformity in the development of the lobulus paraflocularis, and this might be associated with the specialisation of the axial and appendicular musculature for the particular type of progression required for life in the water. (6) It was quite possible to homologise the various subdivisions of the human cerebellum with the accepted constituents of the schematic cerebellar patterns. (7) The sulcus horizontalis magnus seemed to be the homologue of the sulcus intercruralis. (8) No definite statement could yet be made as to functional localisation in all the lobules of the cerebellum. (9) The study offered but little confirmation of the accepted functional capacities of the anterior lobe of the cerebellum. (10) Lobulus 4 and lobulus C, with their associated hemispheral expansion, showed the greatest progressive differentiation and efflorescence. It was definitely associated with the part played by the cerebral cortex in its influence over cerebellar unfolding, and might be correlated with the perfection of the patterns for skilled movements and unilateral independence of the fore and hind limbs. (11) Elaborations of this study might present material of value in further attempts to establish functional localisation in the cerebellum.

Dr. L. J. POLLOCK (Chicago) read a paper by himself and Dr. L. DAVIS on the physiology of the cerebellum. It set out the results of a series of studies on reflex patterns obtained from animals which had been de-cerebrated by an anæmic method. The paper was illustrated by the kinematograph.

Dr. A. T. MUSSEN (Baltimore) set out experimental results, also by moving pictures.

Dr. T. H. WEISENBURG (Philadelphia) dealt with the clinical aspect. He said there was no more controversial subject in neurology to-day than the function of the cerebellum. The same remark also applied, to some extent, to the interpretation of symptoms arising from lesions of this organ. The reason for this lay, in part, in the nomenclature used to describe local disturbances arising in cerebellar disease. Rarely did two authors employ the current terms to convey exactly the same meaning. The chief reason for this was that cerebellar disturbances were manifested in disordered movements, and those movements did not lend themselves to easy description. When he began to study movements with the kine-

matograph he found that his clinical interpretations had been no more than general impressions. There was, he thought, abundant clinical evidence that cerebellar localisation existed. Most authors seemed to be content if they diagnosed a cerebellar lesion, without particularising further. In his own cases he had made more errors where the cerebellar symptoms were obvious—e.g., in tumours of the third ventricle or tumours accompanied by intracranial pressure with involvement of the cerebellum—than in cases showing limited cerebellar functions. In the latter he had made a focal diagnosis, which had been confirmed post mortem. It was often said, in connexion with the cerebellar gait, that it made little difference whether the eyes of the patient were open or closed. He had asked a cerebellar patient to walk across the stage with his eyes open, and found that the patient instinctively corrected his gait by his sight and hearing. When blindfolded he corrected the gait by his hearing. When the patient was blindfold and absolute silence was observed the true cerebellar gait at once became manifest. Moving pictures had enabled him to differentiate various kinds of gait. From the peculiarities of the gait he considered that certain clinical deductions were justifiable. When trunk movements were involved it meant there was a lesion in the thalamus; when the patient staggered backwards probably the anterior or inferior portion of the thalamus was implicated. If the upper part of the trunk was involved the lesion was probably in the superior vermis. He had not seen any instance of the lesion being limited to the right or left lobe. In cerebellar patients it was possible to find dysergia of the arms and legs alone; he had seen cases in which disturbances of arms and legs occurred without involvement of trunk. He agreed with Hughlings Jackson that the cerebellum did not act alone, but functioned in association with other levels and in conjunction with the lower levels in the spinal cord. There was, he contended, a difference in the symptoms of a case according to the lesion present.

Dr. LAURETTE BENDER spoke of her researches in Holland on localisation of control of the vocal cords. In the normal dog, before operation, the vocal cord movements were seen to correspond with the respiratory rhythm. Accessory movements not synchronous with respiration could be demonstrated immediately after the operation and disappeared a little later. The dogs were allowed to live 18 days after their recovery, and when their brains were examined lesions were found in the vermis and the roof nuclei and in the tissues surrounding the fourth ventricle. It was concluded that lesions in the cerebellum could produce disturbances of the cerebellar ataxic type in vocal cords, but these did not occur unless the lesion involved the tracts connecting the cerebellum with the medulla. Control of the vocal cords was not localised to any particular part of the cortex or the roof nuclei.

Discussion.

Dr. F. M. R. WALSHE (London) said that the outlook on the problem of cerebellar function was now distinctly more hopeful. The best knowledge on the sensitive component of the cerebellar functions was due to Gordon Holmes. It had been necessary to rule out volition and study the behaviour of decerebrate animals, and it was to the study of such decerebrate animals that the profession owed what knowledge it had gained. The cerebellum was not responsible for regulation of tone, posture, or equilibrium, and there was no cerebellar ataxy. A close functional relationship had been found between the cerebellar and the cerebral cortex, and it might be that the cerebellum found its function in the process of synthesis and analysis.

Dr. GORDON HOLMES (London) said that defect symptoms of the cerebellum could only be obvious when the brain was intact, and the functions of the cerebellum, looked at clinically, must be closely related to those of the fore-brain. He held that nystagmus was a relatively constant symptom of cerebellar lesions, and that it could proceed from a lesions in the cerebellum alone. Some time ago he had collected all the cases of local lesion of the cortex of the cerebellum which were recorded in the notes of the National Hospital, Queen-square; there were about 20 of them, and he was unable to discover evidence of focal representation of parts of the body in the cortex of the cerebellum, though there was no doubt that when the vermis and mesial portions of the cerebellum were injured there was a greater tendency to disturbance of speech and trunk movements and attitudes. In no case had he ever found definite evidence that a local lesion of any portion of the lateral lobes would produce exclusive, or even predominant, affection of arm or of leg, though there was no doubt in his mind that a cerebellar lesion affected the upper limb more than the lower. Still affection of isolated movements of the lower limb was a cause of disturbance of gait, not characteristic nor invariable, but common in local cerebellar lesions.

Dr. KINNIER WILSON (London) said that skew deviation of the eyes was a comparative rarity in cerebellar disease, but was occasionally seen. Early in his work at Queen-square he had photographed a case with skew-deviation which had come on after an operation performed on the same day by Sir Victor Horsley. That deviation Horsley had attributed to a lesion of the superior peduncle. By skew-deviation he meant one eye going down and in and the other going up and out. It had always seemed to him that this movement was such as might be expected if the eyes were turned in order to correct an apparent movement of the head. It was almost impossible to get this in the human subject, excepting under pathological conditions, but he showed a toy dog whose head would move though its eyes were fixed. If this toy were tilted to one side the eyes took up the position of skew-deviation. The lesson of that was that if for some reason the head did not move, under pathological conditions, deviation of eyes was a compensatory movement.

CLINICAL MEETING.

At a clinical meeting on Wednesday afternoon Sir JAMES PURVES-STEWART (London) showed a boy aged 18, who had a Blood Cyst Located by Pneumo-radiograms. At 12 years of age he had cerebral concussion after falling on the ice, and four months ago he had developed headache and diplopia with no apparent cause. Visual acuity was not diminished but the optic discs were somewhat blurred. There was paresis of the right external rectus and of the left side of the face. The optic discs swelled progressively and the blind spot in each eye was slightly enlarged. Pneumoradiograms showed displacement of the right lateral ventricle towards the left. Therefore a wide decompression was done in the right frontal area, and a subdural cyst the size of a turkey egg, containing blood and altered blood, was evacuated. Since that operation the clinical improvement had been uneventful.

Dr. GORDON HOLMES showed a boy, aged 14, who habitually fell on hearing a noise. He came of healthy stock, no member of the family had a similar affection; he always had good health, and had always done well at school. At 5 years of age he was observed to fall on hearing an unexpected noise or on being startled, even on being suddenly touched from behind. He often sustained fractures on these occasions. There was no change of colour, vertigo, or giddiness; his limbs suddenly flexed and he fell, but he could usually rise at once without assistance. Treatment by means of thyroid, pituitary, bromide, and luminal produced no benefit. A radiogram revealed a rather small sella turcica. He was unnaturally fat, but took little exercise. His skin was rather hairless, but the sexual organs were well developed. When in hospital he had an epileptic attack during sleep, the eyes deviating to the right. He did not lose sphincter control nor bite his tongue, but sometimes he had some soreness of his tongue in the morning. A gun fired behind him at the meeting did not cause him to fall.

Dr. W. J. ADIE said he had long been interested in all kinds of sudden attacks, but had seen nothing like those of this patient. He did not think Dr. Holmes's

se was one of narcolepsy, in which if the patient saw e funny side of something and laughed heartily he ll. Anger and annoyance also caused falling. either had this boy any attacks of inevitable sleep. homsen's disease might cause sudden falling of this ind. The case seemed to be in a class by itself.

Dr. WEISENBURG pointed out that these patients uld resist the manifestation of their peculiarity if nusual circumstances were present, such as those the meeting; he had experienced the same peculiar nial in emotional cases.

Dr. C. L. DANA (New York) said he had seen a mber of cases similar to this and had termed the ndition "falling sickness." He felt sure that they ere epileptic in type.

Dr. C. P. SYMONDS (London) showed a boy, aged 12, ith Schilder's encephalitis. At 2 years of age he gan to have fits, which, the mother said, usually gan as convulsive twitchings of the right side of e face, the right arm, and leg; the twitchings came generalised and the patient lost consciousness. e seemed to be mentally backward and was nervous. o other signs developing, he was discharged with the agnosis of Jacksonian epilepsy. In July, 1919, he as readmitted as he had had a left-sided Jacksonian tack. It was then seen that he had optic atrophy th defective vision, especially in the lower part of e fields. Cerebral tumour was provisionally agnosed, and he was discharged. In September, 22, he had a series of convulsive attacks, chiefly the right side. A younger brother had died of hilder's disease, as proved post mortem.

Dr. ADIE showed three cases. The first was e of Familial Periodic Paralysis. The patient was boy of 13, who often on waking in the morning was able to move hand or foot or to speak. Gradually e weakness passed off, the passing occupying from ree to four hours to two days. The number of acks averaged about one a fortnight. The father d had similar attacks since the age of 4.

The second was a case of Myasthenia Gravis in a y of 10. The onset, two months ago, was rapid. ere was double vision and a generalised weakness of voluntary movements. There was no muscular sting nor fibrillation. The tendon responses were much diminished and the plantar responses were ntar flexor. X rays did not show any enlargement the thymus.

Dr. BERNARD SACHS (New York) suggested that a agram be taken through the open mouth so as to ermine whether there was a fracture of the ntoid process. He quoted a case with similar nptoms in which such a fracture was found.

Dr. DOUGLAS MCALPINE (London) showed a case Syphilitic Amyotrophy in a woman aged 53. teen years ago the patient noticed a weakness of ankles, in consequence of which her feet gradually pped, to the accompaniment of cramp-like pains the legs. Thirteen years ago the left hand, and r the right, became weak in the same way, and the scles of the hands became wasted. No history could obtained of tabetic pains, diplopia, or sphincter dis-lity. The onset suggested a polyneuritis.

Dr. DANA said he had seen several cases of loco-tor ataxy develop typical progressive muscular ophy.

Dr. W. B. CADWALADER (Philadelphia) said that ny patients with chronic tabes of the extreme xic type had considerable muscular wasting, and ny were alcoholic. In some there was doubtless an holic multiple neuritis superimposed on the philitic process.

Dr. ANTHONY FEILING (London) showed a case of netic Facial Paralysis. The boy, aged 8, showed unusual condition of defective innervation of the scles of the right side of the face. He preserved untary power to innervate his facial muscles on h sides, but there was nearly complete paralysis of vement on the right side of his face for emotional ressions. If he were asked to show his teeth he oluntarily screwed up both eyes equally well.

Mr. LINDSAY REA (London) showed patients with extra-ocular paralysis of sudden onset. There were, he said, two types, one of them "rheumatic" and seen chiefly in young women. The first patient had three attacks which cleared up with salicylic acid; then, as that failed, her teeth were seen to, and she had not had another attack in the intervening three years. In the other type, with similar manifestations, the blood pressure was always raised.

Thursday morning was devoted to a discussion on

SENSORY DISORDERS IN ORGANIC DISEASE OF THE NERVOUS SYSTEM.

In view of the illness of Sir Henry Head a message was sent to him referring to his classical contributions to the knowledge of the sensory nervous system.

Prof. J. S. B. STOPFORD (Manchester) said that his experiences favoured Head's interpretation of cutaneous sensation, but he thought that some modification of that authority's views were necessary in regard to deep sensibility. Deep sensibility did not seem to be in accord with any other of the divisions of cutaneous sensation, nor to represent any stage in the phylogenetic history of sensation. This was because more had to be learnt about deep sensibility; there were two stages, comparable to those seen in cutaneous sensibility. After the division of a posterior root an intermediate zone was found in which protopathic sensibility was lost and epicritic sensibility was retained, the reverse of what was seen after division of a peripheral nerve. There was strong evidence that two distinct and independent systems existed, and it was possible for one group of elements to be retained and the other lost. And recovery after successful suture of a peripheral nerve took place in two stages. He had never yet seen a perfect recovery of epicritic sensibility after secondary suture which involved resection of a piece of the nerve trunk. In some parts of the body one of the systems alone was present—e.g., in the glans penis, where there was only protopathic sensibility. If definite pressure was exerted on the glans pain suddenly emerged, of a diffuse and very disagreeable type.

Dr. WILFRED HARRIS (London) dealt with sensory disorders due to spinal and brain-stem lesions. He said that lesions of the posterior columns and the anterolateral and anterior columns, as well as of the central grey matter and posterior root-zone, caused sensory changes of various kinds. Gunshot or stab wounds might be limited to one side of the cord or to the posterior columns, or they might afford useful evidence in the differentiation of function of the afferent spinal tracts. In the slighter cases of myelitis, or in the recovering stage, differentiation of sensation was often met with. Total anæsthesia to all forms of tactile sense—pain, pressure, and temperature—was rare in association with cord lesions, except in acute softening, ascending myelitis, tumour, wounds of the cord, or fracture-dislocation. Pain and temperature might be more involved than tactile sensation, and frequently the Brown-Sequard syndrome might be demonstrable. Excessive sensitiveness to a scratch might be seen at a stage of protopathic recovery of an injured nerve, and paræsthesia, tingling, numbness or formication of the legs were common.

Dr. GORDON HOLMES discussed sensory lesions due to spinal and cortical lesions. He said that Head and he had come to the conclusion that there were many qualities of sensation which could come to consciousness without the intervention of the cortex, and these were attributed to the optic thalamus. Certain portions of the brain-stem could also be engaged in it. Certain qualities of sensation were never completely abolished by a cortical lesion, and this was particularly true of pain. In many extensive cortical lesions there was an alteration to sensibility to pain over the corresponding areas of the body. In intelligent patients it could be proved that it was really in the nature of a qualitative change. He believed that the actual sensation of pain was never lost. Sometimes associated with typical cortical loss hysterical phenomena were encountered. With tactile sensi-

bility the question was more difficult, and some reliable form of æsthesiometer was required. Hallucinations were frequent and tended to vitiate the inquiry. Sometimes on ceasing to touch the patient he would delay his indication of the fact for seconds, even minutes. He thought the explanation lay in the fact that the normal cortical inhibitions of the thalamus had gone, whilst the lower subcortical levels remained in an active state; in other words, it was a release phenomenon. Dr. Holmes appealed for a more common use of the compass-test in examining ordinary cases of suspected cerebral disease; he had found it very important. He had had four cases recently in which it showed the only form of sensation which was disturbed. In three of those the lesion was near the apex of the hemisphere.

Head recognised three functions of the cerebral cortex: (1) appreciation of relationships in space; (2) faculty of reacting appropriately to stimuli of differing intensity; (3) recognition of similarity and difference. As to the part of the cortex which was concerned with sensation, Dr. Holmes said he did not think any portion of the cortex in front of the fissure of Rolando had any direct sensory functions. He considered that the sensory cortex extended considerably backwards to the anterior limb of the supramarginal gyrus. The more direct forms of sensation, such as the tactile, lay anteriorly, and the sense of position probably lay behind this; the more complicated qualities, such as recognition of form, were more posterior, towards the apex of the hemisphere.

Dr. KINNIER WILSON contributed a paper entitled

Certain Dysæsthesiæ and their Neural Correlates.

Complaints of tingling, numbness, and pins-and-needles were, he said, met with daily by every practising neurologist, but it was seldom asked what was the basis for these sensations. They were called "subjective," but this was a bad term, seeing that all sensations were subjective. People described as subjective sensations in which, objectively, they failed to find any particular change in sensibility. One could not know what were the sensations of a patient with a thalamic lesion unless he described them; and if he could do so the way must be open between the thalamus and the speech mechanism. He spoke of the condition present in elderly women who had had a hard-working life and who held their hands in a slightly flexed position and complained of dysæsthesia, mostly at night. He attributed these symptoms to a relative ischæmia. Another group was that of acro-asphyxia and acrodynia. There was a variety in which unbearable pain in the hands was experienced, associated with other phenomena of vascular character. In thalamic cases dysæsthesia was very common. He had never seen dysæsthesia of pain in a cortical case, but he had seen one of the pins-and-needles variety, certainly of cortical origin, and one of thermal dysæsthesia as an aura to a Jacksonian fit. He thought the question of the relation of the vascular and sensitive systems should be approached again. For instance, there were cases of venous neuralgia, which only Edinger, he believed, had referred to. He concluded by raising the question of the value of periarterial sympathectomy, and quoted a case in which unbearable pains in the limbs, unaffected by other treatments, including injection of alcohol, were cured by sympathectomy.

Dr. POLLOCK discussed the influence of overlapping function from adjacent nerves in the return of tactile sense after nerve severance.

Dr. SIDNEY SCHWAB (St. Louis) said that any logical attempt to study pain must be concerned with the person who was subjected to that sensation. The problem of sensation must always be associated with that of the awareness of the individual. States described by patients were so described according to their ability to give a description. Often dysæsthesiæ were related to somatic delusions, and he recommended a study, from this standpoint, of hypochondriasis.

Dr. CASA MAJOR said that the sensory examination of a patient must be, in part, subjective, for the doctor's knowledge must depend on the information which had sifted through the consciousness of the patient. He discussed the question of the point at which differentiation of types took place.

Dr. WEISENBURG pleaded for an uniform method of examining patients and recording the results, as well as a better systematised terminology. The discussion was continued by Dr. K. A. PETRÉN (Lund) and Dr. B. BROUWER (Amsterdam).

On Thursday afternoon the following papers were read and discussed:—Dr. ADOLF MEYER (for the late Dr. C. B. Dunlop, New York): Pathological Changes in Huntingdon's Chorea. Dr. S. KINNIER WILSON: A Case of Senile Chorea. Dr. PURDON MARTIN: A Case of Hemichorea resulting from a Small Cerebral Hæmorrhage. Dr. J. G. GREENFIELD and Dr. RUBY STERN: On the Anatomical Identity of the Werdnig-Hoffman and Oppenheim Forms of Infantile Muscular Atrophy. Dr. GILBERT BECK and Dr. J. G. GREENFIELD: Diffuse Myelitis with Optic Atrophy. Dr. C. WORSTER-DROUGHT and Dr. CARNEGIE DICKSON: A Case of Hypopituitarism (Lorain type).

HUGHLINGS JACKSON LECTURE.

Dr. CHARLES L. DANA (President of the American Neurological Association) concluded the proceedings by delivering the Hughlings Jackson lecture. To his great regret, he said, he had never personally known Dr. Hughlings Jackson, but the whole profession was aware of his great intellectual endowments, his great contributions to neurology, and his charming character. Science in many instances had advanced by learning what had been done in the past; a further view ahead was obtained by standing on the shoulders of those who did epoch-making work.

Speaking of the early days of neurology in the United States, he said that in those days it was often thought that the special function of neurology was to make people think they were safe; it was felt that if anyone was nervous it was due to his own fault of continual introspection—a view which had now entirely disappeared even to-day. American neurology in its virile state, could be said to have been the fruit of the Civil War, to which Weir Mitchell, Hammond, and W. Keen owed much of the wealth of material on which their enlightened practice and their writings were based. Many believed that war was the foster-mother of medicine, and certainly the recent world war seemed to have given a tremendous impetus to neurology, and in America had added greatly to the number of men taking it up as a specialty. In future their work would most usefully lie along the course of prevention, a subject which had been too much neglected. For many nervous diseases there was no cure, rightly so called; hence the high importance of establishing on a large scale methods of prevention. Dr. Dana concluded his lecture by speaking of what was popularly termed the nervous constitution. What was meant by nervousness? To the lay mind it meant an exaggerated mental and physical activity; the patient said he could not sit still, could not prevent himself or herself thinking all the time. There might be present also discomfort and much futile effort. He considered, however, that the nervous temperament was the highest form of constitutional make-up; it was well to have some degree of nervousness in a community. He preferred it to the lymphatic or melancholic constitution. Out of this nervousness might be developed a mechanism by which life extended its capacity and enlarged its vision, and he thought that efforts should not be made to prevent neuroses by developing a lymphatic, slow temperament. He believed in the functional activity of the mast-tissue of the body.

Sir CHARLES SHERRINGTON, in proposing a cordial vote of thanks to Dr. Dana, spoke appreciatively of the experimental neurology done in America. Dr. Dana's name, he said, was intimately associated with this advance in his own country, as well as with a charming hospitality which had always been extended to those who crossed the Atlantic from England.

"Audi alteram partem."

OOD FACTORS IN RELATION TO PREVENTION OF DISEASES OF THE TEETH.

To the Editor of THE LANCET.

SIR,—May I be permitted to emphasise the nportance of the paper on this subject by Dr. J. im Wallace published in your last issue? Therein e conveys a lesson of supreme importance to our rofession, one which, if duly heeded, will prevent n immense amount of disease and suffering.

His message is just this: That caries is initiated y the corroding action on the teeth of acid generated y the fermentation of saccharide food, that the outest tooth is no more capable of resisting this rroding action than the feeblest, that every tooth erforce decays at those parts of it where saccharide od remains in prolonged contact, and that no tooth ecays if kept clean. In short, *dental decay is wholly reventable by dental cleanliness.* It is for us to see iat this pregnant truth is brought home to the mmunity.

No one who has studied Dr. Wallace's paper with n open mind can well fail to be convinced by his guments. Unfortunately there are still some who cline to the older view—that dental decay is largely ie to inherent lack of resistance on the part of the eth, and that its disastrous prevalence in this untry is due to such inherent weakness, the result a deficiency of vitamins, or what not, in the national et. In view of the evidence brought forward by r. Wallace I cannot but think that those who aintain and propagate this view incur a grave sponsibility by encouraging the popular belief that eth decay of themselves, as it were, no matter what ecautions are taken, whereas it can be stated with athematical certainty that teeth, if properly cleansed, not decay.

I am, Sir, yours faithfully,

Harley-street, W., August 1st. HARRY CAMPBELL.

DIET AND DIETISTS.

To the Editor of THE LANCET.

SIR,—The controversy that is taking place in your lumns is certainly confusing to the members of our ofession and more so to the general public. Certain atements are made by the advocates of white ead which do not coincide with experimental dings.

Within the last few years I have carried out at ast 400 feeding experiments myself, and I have en allowed by Prof. Drummond and Prof. Plimmer see the results of their feeding experiments, and for e life of me I cannot understand why there should any doubt whatsoever as regards the value of amin B in nutrition. The tests are very simple. ey have been carried out by many experimentalists; ey have been published over and over; yet there mes on the scene in the form of a manifesto that r diet, using white bread, is perfectly safe. Why es not a committee choose either Prof. Drummond Prof. Plimmer to carry out under the observance three well-known physicians a test with feeding white bread and feeding on wholemeal bread? personally, am unable to keep my rats alive longer an five weeks on a B-deficiency diet. If I add per cent. of wheat germ to their diet my animals e almost indefinitely. This surely is ample proof at white bread is deficient in its vitamin content. Dr. Hallilay's results, which he gives in your last ue, of the effects of wholemeal on the population the Punjab should also be convincing, and I quite derstand the absence of appendicitis, or at least e smaller percentage of appendicitis, amongst the abitants of the Punjab than amongst the white population of India, as anyone who has the least knowledge of deficiency diseases must have noticed the atrophy of both the longitudinal and circular muscles of the intestine and the marked atrophy of the mucous membrane that must lead to stasis with the resulting infection of the appendix.

I am, Sir, yours faithfully,

M. J. ROWLANDS.

The Knightsbridge Laboratories, Sloane-street, S.W., July 29th, 1927.

COLOUR TESTS FOR VITAMIN A.

To the Editor of THE LANCET.

SIR,—Dr. Peacock has raised several points of importance on which we should like to comment.

First, in regard to the data employed to express the dosage of ultra-violet rays. The time (duration) of exposure and the distance of the irradiated material from the lamp supplying the rays are the data commonly used (e.g., in light clinics) throughout the country to measure amounts of irradiation. These data were therefore included in our brief account of the destruction of vitamin A in cod-liver oil by direct irradiation, which was described in greater detail in a paper published recently in the *Biochemical Journal* (1926, xx., 1292). We had, however, appreciated the fact mentioned by Dr. Peacock, that the amount of irradiation is also affected both by the type of lamp employed and by fluctuations in its efficiency. We were much interested in his further data regarding his own experiments, and particularly in his method of registering the output of the lamp by means of an ammeter and voltmeter. It would be valuable to hear the experience of other investigators who have used power consumption to measure the amount of irradiation. In our own case, by courtesy of Dr. R. A. Morton, this measurement of the output of ultra-violet rays has been made by the use of actinometers of various types, in which the rays produce specific chemical changes, such as the conversion of potassium nitrate into potassium nitrite, or the decomposition of oxalic acid, whose reaction products can be estimated chemically. An advantage of these actinometers would seem to be that, since the different chemical reactions are activated by rays of different wavelengths, it is possible, by using different reactions, to measure the output of energy in different parts of the ultra-violet spectrum, a result which could not be obtained by the use of power consumption as a criterion.

At the time of writing the above-mentioned paper on colour tests, the technique of using these actinometers had not advanced sufficiently to justify their mention. We could thus only state the type of lamp used and the fact that its output of ultra-violet rays had been shown by control experiments to be reasonably constant. Later results with actinometers, however, have shown that in the case of certain lamps there may be a loss of more than half the efficiency within a few weeks of putting them into use, and we would strongly endorse Dr. Peacock's suggestion for the establishment of international units for measuring the efficiency of all lamps employed as sources of ultra-violet rays.

A second point to which we would draw attention, and on which Dr. Peacock has obtained results supporting our own investigations, is the effect of irradiation in rendering vitamin A unstable. In your leading article of July 2nd it was pointed out that in irradiating milk to produce vitamin D there is danger that this may simultaneously cause the destruction of vitamin A, as was first shown to occur in butter by Zilva in 1919. At the outset of our investigations we hoped to overcome this difficulty by cutting down the period of irradiation to a point at which a valuable amount of vitamin D would be produced but no significant amount of vitamin A destroyed. Unfortunately, this hope had to be abandoned when we discovered that after a vitamin A-containing substance such as cod-liver oil had been

exposed to ultra-violet light even for a few minutes only, there was produced in the oil some substance, possibly of the nature of an organic peroxide, which continued to cause the destruction of vitamin A. An initial loss of about 3 per cent. of the vitamin had increased in three months' time to about 25 per cent., and after six months there was very little of the vitamin left. This observation raises serious difficulties in the commercial application of irradiation methods to foodstuffs on a large scale.

A consideration of various experimental results has led us to take great interest in the close connexion between vitamins A and D, especially in regard to the action of light under different conditions. In the case of spinach, which has long been known as a potent vegetable source of vitamin A, it has been demonstrated that the original low content of vitamin D can be markedly increased by exposure of the leaves to the action of ultra-violet rays, either those present in sunlight or artificially produced. On the other hand, the ultra-violet rays, either in sunlight or artificially produced, have been found by Dr. Peacock and ourselves to destroy vitamin A in cod-liver oil. From the recent work of Dr. Coward, however, it would appear that ultra-violet light can accelerate the formation of vitamin A in living plant tissues. From this it would also appear that the action of sunlight on vitamin A is probably different in living and in dead tissues. Many interesting and important questions arise from these observations, if they are confirmed. Is the wave-length of the rays which destroy vitamin A the same as that of the rays which produce vitamin D? Are vitamins A and D derived from the same parent substance? Do the pigments in the living plant play a part in selecting the particular rays which produce vitamin D? These and other questions suggest themselves at once for consideration in future applications of ultra-violet light both to food materials and in actinotherapy.

We are, Sir, yours faithfully,

STANLEY G. WILLIMOTT.
Cambridge, July 22nd. FRANK WOKES.

TETANUS FOLLOWING INTRAMUSCULAR INJECTION OF QUININE.

To the Editor of THE LANCET.

SIR,—It always seems to me that the cause of tetanus after intramuscular injection of quinine is a rusty hypodermic needle. On the west coast of Africa where tetanus spores are common I have made many injections of quinine without mishap. I have used a platinum needle and have refused steel needles, because when once damp they always go rusty inside even if kept bright on the outside.

There is another point. Intramuscular injection of a dense solution of quinine causes a necrotic nodule in goats and I have no doubt the same is produced in human beings. I therefore use bihydrochloride of quinine, one part dissolved in eight or ten of water. There is no need for prolonged boiling. Ten grains of the quinine salt in 80 drops of water and brought once to the boil is sufficient. Similarly a teaspoon and a hypodermic syringe and platinum needle brought once to the boil suffice for the apparatus. The test-tube containing the quinine solution should be stopped with flamed wool while it cools. The teaspoon is to pour the solution into so as to get it into the syringe. I rub over the puncture made by the needle with tinct. benzoin. co. or collodium, as what between the sweating of the patient and an occasional drop of blood which comes on withdrawing the needle it has seemed to me that infection by the puncture is possible.

I am not here considering the intracellular solidifying injections of quinine which I recommended many years ago [1] for the purpose of securing a few months' immunity from malaria in negro children.

I am, Sir, yours faithfully,

Linden-gardens, W., August 1st. G. F. DARKER.

MEDICAL PRACTICE IN COLOMBIA.

To the Editor of THE LANCET.

SIR,—In your issue of June 18th, under the headin Practice Abroad, it is stated that "In Colombia a unqualified person can in certain circumstances obtai permission to practise medicine but not surgery. May I state that in accordance with recent legislatio nobody can under any circumstances get permissio to practise medicine without being qualified.

Article 3 of Law 85 of 1922, which deals exclusivel with the medical profession, reads as follows:—

"Foreign doctors in possession of diplomas granted abroa are allowed to practise medicine in Colombia provided th they can show their academic title legalised by a diplomat or consular agent for the Republic in the country of t origin of the said title and provided that they can personally identified and pass a theoretical and practic examination directed by the examining board created by th Law in accordance with the following conditions:" (He the conditions are mentioned in detail.)

The above Law is published in pages 267, 268, and 26 of the Official Book issued by the Congress in 192

The provision mentioned in your article refers very special cases and is only applicable to Colombian These cases are defined in Article 11 of the said La which stipulates that in a village where there is certified doctor permission can be given to a pra titioner to perform the duties of a doctor.

I am, Sir, yours faithfully,

J. MEDINA,
Director, Colombian Government Bureau of Information and Trade Development.
7, Sicilian-avenue, Southampton-row, London W.C., July 19th, 1927.

PATHOLOGICAL LABORATORIES AND THE B.M.A.

To the Editor of THE LANCET.

SIR,—At the annual representative meeting of t British Medical Association, held on July 16th la the following resolution is reported to have be passed unanimously:—

"That the Representative Body disapproves of the esta lishment by trading firms of laboratories as subsidia enterprises for the purpose of offering pathological exami tions and reports on individual cases, and advises membe of the Association to avoid any association with su enterprises."

Inasmuch as this might be taken to apply to a pathological laboratory established by a commerc firm, the Virol Pathological Research Laborator wish to place before you the following statement reply.

These Laboratories were established by Virol L 14 years ago in order to provide for registered medi practitioners—to whom the services of the Laborator are confined—pathological tests at a scale of fe which should be within the reach of patients of limit income, and for research in clinical pathology. Duri this period over 2000 medical practitioners a 400 public health authorities have availed themsel of the services of the Laboratories.

The Laboratories are under medical control a have no connexion with the commercial side Virol Ltd. The fees accruing from patholog tests have been devoted, after payment of establi ment charges and salaries, to research in clini pathology. No proportion of the profits has be received by Virol Ltd. As regards research, numer investigations have been conducted by the staff, records of which have been published in the medi press of this and other countries. All reports and always have been signed by one or more qualif medical men, thus fixing responsibility for the opini expressed therein. They are issued only to registe medical practitioners and never to patients direct.

On the question of competition with priv pathologists, which was raised at the meeting of Association, it may be observed that this, so far it occurs, is inherent in the difference betwee large laboratory and a single worker. In the c

the former, the staff consists of investigators
ıo have specialised in different branches of patho-
ɣy, so that any given specimen can be examined
ɔm the bacteriological, serological, biochemical,
ematological, and histological points of view. In
her words, the opinion given is that of a "team"
d not of one man only, who is seldom himself
pert in all branches of pathology. Furthermore,
e provision of laboratory facilities for patients of
nited means is rendered possible only by the receipt
a large number of specimens—many more, in
ɔt, than a single pathologist could examine. It
llows that the private pathologist receives from
s patients higher fees for the tests he performs.
ith this branch of practice the Virol Pathological
esearch Laboratories do not compete.

It is regrettable that this wholesale condemnation
"commercial" laboratories should have been
ade without any discrimination in regard to the
ture and quality of the work performed, and
tirely ignoring the important point as to whether
e services of any given laboratory have been
und of value to medical practitioners in the diagnosis
d treatment of disease, at fees which their patients
n afford to pay.

I am, Sir, yours faithfully,

A. KNYVETT GORDON, M.B.,
Medical Superintendent, Virol Pathological Research
July 30th, 1927. Laboratories.

EDICAL SCIENCE IN THE CITY OF YORK.

To the Editor of THE LANCET.

SIR,—"The long and intimate connexion of the
y of York with medicine and surgery," to which
ference was made in the issue of THE LANCET of
ly 9th (page 78), is a subject the study of which
uld well repay the medical historian. Few cities
ve an equal record of illustrious physicians and
geons who have earned fame in their day and
neration. The Gild of Barber-Surgeons of the City
York existed from the twelfth century, and the
ries in the roll of freemen contain seven names of
ber-surgeons from the year 1299. That they
ained eminence in their profession is proved by an
ry in the exchequer accounts of John Wodehouse,
der date 1346: "Payments to Master William
Bolton (freedom 1318) and Hugh Kelvington
edom 1348), barber surgeons, going from York to
Castle of Bamburgh to heal the said David de
s, who lay there, having been wounded with an
ow in the said battle [Neville's Cross] and to extract
arrow and heal him with dispatch, £6." William
Bolton was a munificent donor to the building of
nave of York Minster, and his arms are displayed
ve one of the arches therein. An Ordinance of
4 has reference to the yearly appointment of a
ster in anatomy who twice during his year of office
s bound, under pain of a fine of 10*s.*, to lecture
n some surgical or anatomical subject, accom-
ied by a practical demonstration upon the cadaver.
this purpose the body of an executed prisoner
delivered at every assize. The master of anatomy
one of the "searchers" once in six weeks coached
apprentices "of all such as practise chirurgerie."
asionally a candidate was failed: "Francis
gham, Mr., but insufficiente for surgerie, and also
ine the xxtie of Aprill, 1615, he is found insufficiente
n full personal consente of the whole Companye."

he ordinances of the Gild are now in the British
eum (Egerton MSS. 2572), but the earliest are
se in Register A/Y, folio 72, preserved in the
hives of the city. In the Minster library is a bound
me of medical MSS. on vellum in different hand-
ings, one of which bears the date 1432. Of
able York medical practitioners a few may be
tioned—e.g., Martin Lister, F.R.S., physician to
en Anne; Theophilus Garencieres; Robert
tie, F.R.C.P. (1632–81); John Gowland,
thecary to George I.; Sir Clinton Wintringham,
sician-general to King George II. at the battle of
ttingen, and his father of the same name, who built
the house in Lendal, with the head of Æsculapius over
the doorway, now used as the "Judge's lodgings"; John Burton, author of "Monasticon Eboracense" and the prototype of Sterne's "Dr. Slop" in "Tristram Shandy"; Francis Drake (1696–1771), author of "Eboracum"; Thomas Fowler, the originator of "Fowler's solution"; John Thurnam, author of "Crania Britannica"; and James Atkinson, surgeon to the Duke of York, whose "Medical Bibliography" the late Sir William Osler described as "one of the most delightful books ever written by a medical man." These are but a few of those who have shed lustre on the medical profession and on the city which harboured them. *Quasi cursores vitai lampada tradunt.*

It may be mentioned that the York Medical Society is one of the oldest existing medical societies in the provinces.—I am, Sir, yours faithfully,

Birmingham, July 16th, 1927. GEORGE A. AUDEN.

POOR-LAW HOSPITALS.

To the Editor of THE LANCET.

SIR,—Mr. Hamilton Bailey's attack upon the Poor-law medical officer in your issue of July 30th would appear to demand some reply from that "degraded" section of the profession. What precisely is meant by "professional degradation" is not entirely clear. Possibly it bears some relationship to that sense of professional humiliation which undoubtedly results not from "being associated with Poor-law" but from the necessity of devoting much time to the attempt to alleviate the dying miseries of surgical failures from the voluntary hospitals.

We are, Sir, yours faithfully,

CHARLES W. BROOK,
FREDK. W. COLLINGWOOD,
RICHARD G. ORAM,
J. L. WOODHOUSE.

Southwark Hospital, July 30th, 1927.

THE LABELLING OF EGGS.

To the Editor of THE LANCET.

SIR,—I was interested in Dr. G. Clark Trotter's letter on this subject in THE LANCET of July 16th, and I thoroughly agree with his remarks. As a general practitioner who is constantly prescribing "new laid" eggs for my patients, I have at times been dissatisfied with them, and knowing the tricks of the trade, as mentioned by Dr. Clark Trotter, in some of my serious cases I have supplied them with eggs from my own fowls. I consider that it is a very serious matter for the public to be deceived as they are; they should know what they are buying. A "new laid" egg should not be more than three or four days old, and very few imported eggs can claim to be this. I would suggest that the safest way for the public would be to have each egg stamped with the name of the country from which it came. I hope that not only medical officers of health but also general practitioners will take up this matter.

I am, Sir, yours faithfully,

A. G. EVERARD, M.R.C.S., L.R.C.P.

Clapham-road, S.W., July 18th, 1927.

To the Editor of THE LANCET.

SIR,—Your readers will, I am sure, be pleased that the misleading labelling of eggs is being ventilated in your columns. The housewife has indeed a difficult task, perhaps one might say almost an impossible one, to make certain that she obtains home produce. From the correspondence, as well as what has appeared in the public press, it is evident that the purchaser is quite commonly misled, and that imported eggs are sold to the farmer for mixing purposes so that the vendor of "home farm" eggs may be deceived. A good case seems to have been made out for marking the imported egg.

I am, Sir, yours faithfully,

E. FAIRFIELD THOMAS, M.D.

Oakley-street, S.W., July 26th, 1927.

CONTRACEPTIVE DRUGS.

To the Editor of THE LANCET.

SIR,—Allusion has recently been made in your columns to the possible effects of a drug such as chinosol on the female genital passages. It has always seemed to me that enough attention has not been given to another possibility in connexion with the use of this and similar drugs. It is common knowledge that their use has not always the desired effect, and the spermatozoon may break through the antiseptic "barrage." Should this occur, it is not unreasonable to suppose that, in a proportion of cases, the germ-cell, while it survives, has nevertheless been damaged. A drug which can kill may in a non-lethal concentration cause injury. A damaged spermatozoon may still be capable of fertilising an ovum, and it would seem almost certain that such a partly poisoned male element must seriously affect the development of the embryo. May it not be that here is to be found the explanation of some of the cases of congenital mental and physical defect? Mental defect, amounting often to imbecility, is found, to a greater extent than I think is realised, among the offspring of the well-to-do, and it is often impossible to ascribe the disaster to hereditary factors; the parents may indeed be above the normal in intelligence. Careful inquiry into the sexual habits might throw more light on the problem of causation in these cases than the tracing of a family history through several generations. There is already some evidence on the experimental side of the effects of damaging fertilised ova in their early stages of development, and it might be worth while to endeavour to observe the action of contraceptive drugs (in spite of the obvious difficulties) in the case of rapidly breeding mammals.

I am, Sir, yours faithfully,

CHAS. E. THORNTON, M.B., B.S.

Rodenhurst-road, S.W., July 26th, 1927.

THE CERTIFICATION OF LUNACY.

To the Editor of THE LANCET.

SIR,—It has already been stated in your columns but deserves iteration that there has never yet been a clear decision by the House of Lords on the question whether the mere grant of a certificate should render a doctor liable to an action for damages. It is not the certificate but the magistrate's order made consequent upon the certificate that sends a patient to the asylum. The magistrate who makes the order is protected *virtute officii* from any form of action; yet his is the hand who signs the warrant. He is not bound to sign it. He may ignore the certificate if he is not satisfied. Why should the doctor who is in reality only a witness upon whose testimony the justice makes an order be exposed, unlike any other witness in any other court, to the risk of an action for damages? As well might the mere witness at the Old Bailey who swears that he saw the prisoner breaking and entering the house of the prosecutor be cast in damages at the suit of the thief.

It is recorded that an old judge who was compelled to decide a case in accordance with principles which he did not approve, ended his judgment with these words: "Had we, the judges, been makers of the law this question had not been. But we are not here to make law but to administer it, and this I say to silence those who would protest against us." In the course of his judgment Mr. Justice McCardie clearly intimated his dissatisfaction with the present state of things when he said: "It may well be that as the result of past litigation many doctors have refused, and would refuse to take any part whatever in the work of certification because of the perils and anxieties of litigation which may occur." Many of those now practising at the Bar would agree with him that some further protective legislation is needed.

I am, Sir, yours faithfully,

July 29th, 1927. LEX.

THE MEDICAL DIRECTORY.

To the Editor of THE LANCET.

SIR,—The annual circular has been posted to eac member of the medical profession. If the form ha not been received, a duplicate will be sent on reques We shall be grateful for the return of the forms b an early post.

We are, Sir, yours faithfully,

J. AND A. CHURCHILL.

7, Great Marlborough-street, W., July 29th, 1927.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AN SURGEONS OF ENGLAND.—At a meeting of the Comitia the Royal College of Physicians and of the Council of t Royal College of Surgeons on July 28th, diplomas of L.R.C. and M.R.C.S. were respectively conferred upon 179 candidat (146 men and 33 women), who have passed the Final Examin tion in Medicine, Surgery, and Midwifery of the Conjoi Board and have complied with the by-laws of the Colleg The following are the names and medical schools of th successful candidates:—

S. I. Abrahams, Guy's; Florence A. Adam, Royal Fre Florence M. Allen, King's Coll.; N. H. C. Allen, Guy' * V. F. Anderson, Westminster; J. H. Attwood, S Bart.'s; Grace L. Austin, Univ. Coll.; I. Bakhsh, Guy' D. S. M. Barlow, Univ. Coll.; W. V. Beach, Guy's; A. C. Bell, St. Bart.'s; J. F. Bell, Liverpool; Constance M. Bishop, Charing Cross; W. Till, Guy's; R. H. Tootill, Manchester; H. A. Tracey, Oxford and St. Bart.'s; * Winifred M. Turner, Royal Free; S. Tyagaraja, Cambridge and St. Thomas's; K. S. A. Venkatachala Ayyar, Madras and Guy's; A. D. Versteegh, Harvard and St. Thomas's; F. L. H. Voller, St. Thomas's; * Joan B. Walker, Royal Free; E. Ward, Manchester; E. N. Wardle, Liverpool; A. G. Watkins, Cardiff and Univ. Coll.; P. H. Whitaker, Liverpool; Margaret A. Willcox, Cambridge and King's Coll.; F. C. Wilson, King's Coll.; W. M. Wilson, St. Bart.'s; J. Woolff, Cape and St. Thomas's; R. L. Wynne, Liverpool; and H. Yousri, Birmingham.

* Diploma of M.R.C.S. was conferred previously.

The undermentioned diplomas were jointly conferred on the following candidates:—

DIPLOMA IN PUBLIC HEALTH.

B. F. Beatson, Elizabeth Bird, Marion Bow, C. E. W. Bower, C. H. Budge, S. C. Chopra, N. P. Dalal, C. J. Donelan, Doris L. Durie, W. C. Harvey, N. M. Hodivala, A. Y. Ibrahim, J. S. Kapadia, Dorothy F. McIntosh, M. S. Mahmood, J. P. Marsden, Doris I. Mart, J. N. Mehra, T. C. St. C. Morton, S. G. Nashikkar, Margaret M. Nolan, Esther Novinsky, R. S. Ralph, H. Ratnarajah, J. L. Stuart, E. V. Suckling, and Elsie Thomson.

DIPLOMA IN OPHTHALMIC MEDICINE AND SURGERY.

A. S. Anderson, M. A. H. Atiya, J. Biggam, Catherine McL. Buchanan, W. B. Clipsham, A. G. Curzon-Miller, Edith Hatherley, E. F. King, V. M. Metivier, F. J. B. Miller, J. H. Moorhouse, W. M. Muirhead, W. D. O'Donoghue, W. J. Robertson, G. Singh, R. G. Stott, S. E. Ward, J. R. Wheeler, and M. Yuille.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—An ordinary Comitia of the College was held on July 28th, Sir John Rose Bradford, the President, being in the chair. The following candidates having satisfied the Censors' Board were admitted as Members:—

Murray McC. Baird, Henry T. Barron, Charles P. Blacker, Vernon H. Brink, Eric B. Brooke, Hugh P. Dawson, Robert van Buren Emmons, Ernest T. D. Fletcher, Alexander W. Gill, Katharine A. C. Gillie, James A. Glover, John G. J. Green, Alice E. B. Harding, George A. Hardwicke, John A James, John W. Joule, George H. K. Macalister, Douglas H. MacLeod, Greer E. Malcomson, Alexander K. Miller, Jessie L. Robb, Wilmot Samarasinghe, Ronald E. Smith, Claude A. Taylor, John H. M. Walker, Edwin C. Warner, Henry L. Wilson, John G. Wilson.

Licences to practise physic were granted to 179 candidates who had conformed to the by-laws and regulations of the College and passed the Final Examination in Medicine, Surgery, and Midwifery of the Examining Board in England. Diplomas were granted jointly with the Royal College of Surgeons to 27 candidates in Public Health, to 12 in Psychological Medicine, to 19 in Ophthalmic Medicine and Surgery, and to 12 in Laryngology and Otology.

The following were elected officers of the College for the ensuing year:—

Censors.—Sir Edward Farquhar Buzzard, Dr. F. J. Poynton, Dr. A. P. Beddard, and Dr. J. W. Carr.
Emeritus Treasurer.—Sir Dyce Duckworth.
Treasurer.—Dr. S. P. Phillips.
Registrar.—Dr. Raymond Crawfurd.
Harveian Librarian.—Dr. Arnold Chaplin.
Assistant Registrar.—Dr. R. O. Moon.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At a meeting of the College held on July 27th, Dr. A. Logan Turner, the President, in the chair, the following 29 candidates, out of 55 entered, who passed the requisite examinations on April 1st, were admitted Fellows:—

Hamish M. Anderson, William A. Nasabushanam Chanmugam, John N. Chesterman, Gopinath Singh Chowdhary, William D. Cruickshank, Praphulla Chandra Datta, Thomas D. Deighton, Eric G. Dingley, Arthur H. McC. Eaton, Henry R. Haigh, Henry W. Harvey, Thomas G. I. James, Victor F. Lambert, William J. Liddle, Ralph Lodge, Herbert Lord, Peter A. McCredie, George McNeill, Wilfred Park, Arthur D. Pegg, George A. Pollock, Nanikram Chartsing Ramchandani, Ronald M. Savage, Julienne Singham, Robert I Stirling, Edward C. Tamplin, John M. R. Thomas, Margaret C. Tod, and Weldon P. T. Watts.

MEDICAL TOUR OF THE FRENCH RIVIERA.—The Medical Society of the Mediterranean Coast has arranged a tour of the French Riviera from Dec. 30th to Jan. 7th next. It will be open to all medical practitioners and their families, and further information may be had from the French National Touring Office, 56, Haymarket, London, S.W. 1.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At an ordinary meeting of the Council held on July 28th, Sir Berkeley Moynihan, President, in the chair, Mr. Thelwall Thomas, the recently re-elected member of the Council, was introduced and took his seat in the Council. Mr. J. Lewin Payne was re-elected a member of the Board of Examiners in Dental Surgery. An offer by the Committee of Management of King's College Hospital to lend permanently to the College Lord Lister's Surgical Notes was accepted.—A letter was read from Dr. A. Primrose on behalf of the Canadian Medical Association thanking the Council for the interest they have taken in facilitating the taking of the examination of the Royal College of Surgeons by candidates from the Dominion of Canada. A letter had been sent regarding the arrangements which might be made for holding Primary Examinations for the Fellowship to the Canadian Medical Association.—The Council have accepted with much appreciation a gift of £5000 from Mr. Buckston Browne, F.R.C.S., to be invested, the interest from such investment to be expended in providing an annual dinner on the College premises for Fellows and Members of the College and such others as the President and Council may wish to invite, at least half the guests invited to be Members of the College.—A sum of £100 was voted for expenses in connexion with an investigation, to be carried out in the museum workrooms by Sir Charles Ballance, with the assistance of Mr. Burne and Mr. S. Steward, regarding the rejuvenation of nerves by the method of tissue culture.

UNIVERSITY OF CAMBRIDGE.—Mr. H. L. Wilson, of Emmanuel College, has been elected to the E. G. Fearnsides Scholarship for the encouragement of clinical research among the organic diseases of the nervous system.

MILROY LECTURES.—The Council of the Royal College of Physicians of London announces that applications for the office of Milroy Lecturer for 1929 must be addressed to the Registrar by Sept. 28th next. Particulars will be found in our advertisement columns.

UNIVERSITY OF LEEDS.—In connexion with the forthcoming meeting of the British Association at Leeds it has been decided to confer the honorary degree of Doctor of Laws upon Sir Arthur Keith, F.R.S., President of the Association (1927–28), and the degree of Doctor of Science upon Dr. John Scott Haldane, F.R.S.

METROPOLITAN ASYLUMS BOARD.—A three months' course of lectures and demonstrations on Clinical Practice and in Hospital Administration will be given at the North-Eastern Hospital, St. Ann's-road, Tottenham, N. 15, by Dr. F. H. Thomson, medical superintendent, on Mondays and Wednesdays, at 4.45 P.M., and alternate Saturdays, at 11 A.M., beginning on Monday, Oct. 3rd. Particulars are obtainable from the Clerk to the Board, Victoria Embankment, London, E.C. 4.

LANCASHIRE TUBERCULOSIS HOSPITAL.—The Lancashire County Tuberculosis Committee has decided to provide more accommodation for the treatment of cases of acute tuberculosis at the Wrightington Hall Estate, near Parbold, where there is about 160 acres of land. The Ministry of Health will recommend a grant of £180 per head towards the capital expenditure involved in the scheme to provide 226 beds on the estate.

APPOINTMENT OF WOMAN POLICE DOCTOR.—The Watch Committee of the City Council of Manchester has appointed Mrs. Nesta Helen Wells, M.B., of Chorlton-on-Medlock, as medical officer to the Manchester City Police Force. This is said to be the first appointment of its kind in the country and is the result of a decision by the City Council some months ago that the examination of women suspects or prisoners should be carried out by a woman rather than by a man.

THE LATE DR. J. S. BROOKFIELD.—Dr. John Storrs Brookfield, who died on July 19th at the age of 82, was a striking figure in the medical school of the University of Edinburgh in the late 'sixties and early 'seventies of last century. He had graduated in Arts at the University of New Brunswick in 1864, and was somewhat older than his contemporaries at Edinburgh, but he entered with enthusiasm into both intramural and extramural activities at the University. He graduated as M.B. in 1871, and became M.R.C.S. Eng. in the same year. In 1873 he proceeded to the M.D. degree. He served as medical officer of health at Penistone, Clayton West, and Huddersfield, and then settled at Kilburn, where he was physician to the Kilburn and St. John's Wood Dispensary. Afterwards he became consulting physician to the Willesden Hospital, and was appointed a justice of the peace for Middlesex. Moving to Upminster, in Essex, he was attached to institutions in the neighbourhood, but for the last few years had been living in retirement.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

THE SUMMER ADJOURNMENT.

PARLIAMENT adjourned on Friday, July 29th, for the summer recess. Both Houses will reassemble on Tuesday, November 8th. Among the measures to which the Royal Assent was given by Royal Commission were the following: The Finance Act; the Diseases of Animals Act; the Poor Law Act; the Midwives and Maternity Homes (Scotland) Act; the Trade Disputes and Trade Unions Act; the St. Mary's Hospital (Newcastle-upon-Tyne) Act; and the Workmen's Compensation (Transfer of Funds) Act. Much information of medical interest was elicited during the concluding days of the session, some of which has been unavoidably held over until our next issue.

HOUSE OF COMMONS.

WEDNESDAY, JULY 20TH.

Treatment of Mental Patients in the Sudan.

Mr. PETHICK-LAWRENCE asked the Secretary of State for Foreign Affairs what facilities existed in the Sudan for the detention and treatment of persons certified as insane; and whether it was the practice in the Sudan to detain such persons in ordinary prisons.—Mr. LOCKER-LAMPSON (Under Secretary for Foreign Affairs) replied: I understand that there are no regular lunatic asylums in the Sudan, but that as regards Europeans mild cases of insanity are dealt with in the hospitals, while violent or dangerous cases are sent to Cairo as soon as possible, being housed in such accommodation as may be available en route, and being admitted to an institution on arrival there. Cases of insanity amongst the Sudanese are always, when possible, sent to their homes, recourse being only had to hospitals, prisons, or such accommodation as is available locally in violent or dangerous cases.

Accident at Liquid Air Company's Works.

Mr. DAY asked the Home Secretary whether his attention had been drawn to an incident which happened to an oxygen receiver belonging to the Liquid Air Company at the Bolton super-heater works, Adswood, in which two men lost their lives; and whether the officers of his department were investigating this occurrence.—Captain HACKING replied: Yes, Sir. The circumstances of this accident have been carefully investigated by the Factory Department. Their report shows that it was caused by the clothing of the two unfortunate men catching fire when they were inside the receiver. There was no sign, however, of any explosion, and it has not been possible to obtain any definite evidence as to how the fire originated. Inquiry will be made into the practice in other works where similar plant is in use with a view to considering what precautions are necessary to prevent any such accident in future. This is the first case of the kind that has come to the notice of the department.

THURSDAY, JULY 21ST.

Noise of Motor Traffic.

Sir ROBERT THOMAS asked the Home Secretary whether he was aware that his warning, issued to motorists last year, that they must more effectively silence their machines, had not produced any appreciable diminution in the noisiness of a great many machines; and whether he would take further action in the matter.—Sir W. JOYNSON-HICKS replied: The hon. Member may be interested to know that in the first six months of this year there were over 5700 prosecutions in the Metropolitan Police District. In any event, the police will continue to take such steps as are possible to abate the nuisance in so far as it still exists.

Sir R. THOMAS: Is the right hon. gentleman not aware that these infernal screeching motor syrens are causing intense mental anguish to hundreds of patients in nursing homes in London, and often causes their deaths; and does he not realise that it is necessary to take drastic action?

Sir W. JOYNSON-HICKS: I do not know what more drastic action I can take than to prosecute 5700 people in six months. My definite instruction to the police is at all times to stop the noise of motor-cycles and motor-cars.

Cream and Food Preservative Regulations.

Mr. LAMB asked the Minister of Health whether it was his intention, before enforcing the Public Health (Preservatives, &c., in Food) Regulations in respect to cream, to introduce the legislation necessary to prohibit the reconstitution of cream so as to give the public the same protection as they now enjoyed in the case of milk.—Mr. CHAMBERLAIN replied: I am informed that it is not necessary to introduce legislation for this purpose, as the existing provisions of the Sale of Food and Drugs Acts would prevent the s of reconstituted cream as cream. The Preservatives Re lations will apply to the substitute equally as to genu cream.

The Milk and Dairies Order.

Mr. ALBERT ALEXANDER asked the Minister of Hea whether his attention had been called to the fact th as stated at a meeting of the Great Yarmouth town coun large numbers of milk retailers in the borough of Yarmo had not yet been registered; and what steps he propo to take to see that the Milk and Dairies Order was enforc —Mr. CHAMBERLAIN replied: My attention had not p viously been drawn to this statement, but I am communic ing with the town council on the subject.

Cost of the Public Services.

Mr. BENNETT asked the Secretary to the Treasury amount per head of the population expended in resp of each of the public services undertaken or contribu to by the State in 1913 and in 1926–27 respectively Mr. R. MCNEILL replied: The amounts issued from Exchequer to meet expenditure in the years 1913–14 1926–27, divided by the population, taken as 45,713, (Great Britain and Ireland) for 1913, and 45,227,000 (G Britain and Northern Ireland) for 1926, are as follows:—

—	Exchequer issues.		Per head of population.					
	1913–14.	1926–27.	1913–14.			1926–		
	£ (millions).		£	s.	d.	£	s.	
National Debt Services	24,500	378,584	0	10	9	8	7	
Other Consolidated Fund Services ..	12,823	40,181	0	5	7	0	17	
Army, including Ordnance Factories ..	28,346	43,600	0	12	5	0	19	
Navy	48,833	57,600	1	1	4	1	5	
Air Force	—	15,530		—		0	6	
Civil Estimates ..	53,901	240,486	1	3	7	5	6	
Customs and Excise and Inland Revenue	4,483	11,514	0	2	0	0	5

Total	197,493	842,395	4	6	5	18	12	

MONDAY, JULY 25TH.

Social Hygiene in Colonies.

Sir ROBERT NEWMAN asked the Secretary of State for Colonies if he would state what steps had been taken to effect to the recommendation of the Colonial Office Advi Committee on Social Hygiene, in their first report is in 1925, that the Government of the Straits Settlem should at the earliest practicable date suppress all bro whenever their existence was discovered.—Mr. AM replied: I have no recent report bearing on this parti part of the Committee's recommendations, but the w problem is receiving the constant and careful attenti the local government in the light of the Committee's re I would remind my honourable friend that the Comm recognised that it could not fix a limit to the time w would be required for the suppression of all known bro

Mr. CECIL WILSON asked the Secretary of State fo Colonies whether he would consider the calling togeth the Colonial Office Advisory Committee on Social Hy with a request that a report should be prepared and i upon methods of dealing with prostitution in Hong-K the Federated Malay States, Malta, and Cyprus.—M AMERY replied: The question of the reconstitution committee to advise me on this subject is now under sideration, but pending a decision as to this I can gi undertaking as to whether it will be possible to deal wit problems arising in all the dependencies referred to i question.

Civil List Pensions.

Mr. HURD asked the Prime Minister whether, in ord provide adequate State recognition of self-sacrificing devoted services to medicine, science, philosophy, literature, he would arrange for an increase in the Civi pension of about £75 for a person now awarde supplement that sum by some other form of recogniti Mr. CHURCHILL replied: The amount which can b tributed in any year is strictly limited by a stat provisions of the Civil List Act. In present circumst I cannot contemplate the introduction of legislation to that arrangement.

Medical Men and Privilege in the Courts.

Dr. VERNON DAVIES asked the Minister of Health attention had been drawn to the decision of o His Majesty's judges at the Birmingham Assize July 18th, 1927, that there was no privilege for m men to refuse information to the court obtained confide in the treatment of a patient suffering from a part

complaint, in spite of definite assurances in the past by the Ministry of Health that such information would be inviolate; and, as this decision by the learned judge must exercise a deleterious effect upon the detection and treatment of this complaint by preventing sufferers seeking competent medical advice and treatment, what steps he proposed to take to implement the assurances given to such sufferers in the past that the information obtained by submitting themselves to treatment would be kept inviolate; and whether, in view of the importance of removing any obstacle to complete confidence between a patient and his medical adviser in the early stages of this disease, he would inquire into the desirability of introducing legislation to give a doctor the right, at least in the case of this disease, to refuse to give evidence about confidential information obtained from a patient.—Sir KINGSLEY WOOD replied: My right hon. friend's attention has been drawn to this case, and he proposes to give very careful consideration to the points raised by it.

Dr. DAVIES asked if the Minister of Health would bear in mind, when considering this question, that it was a matter dealing with panel patients, and that it might have very deleterious effects on the treatment of disease and lead to a feeling of insecurity both among medical men and their patients.

Sir K. WOOD replied that there were many difficult questions, to which the Minister of Health proposed to give very careful consideration.

Death-rates in West Ham.

Miss LAWRENCE asked the Minister of Health whether he would give the death-rate for 1000 living for the county borough of West Ham for the quarters ended March 30th and June 25th for the years 1926 and 1927.—Sir KINGSLEY WOOD replied: The provisional figures are as follows: For the 13 weeks ended April 3rd, 1926, and April 2nd, 1927, 12·7 and 15·3 respectively; and for the 13 weeks ended July 3rd, 1926, and July 2nd, 1927, 9·9 in each case.

TUESDAY, JULY 26TH.

Deaths in the Chinese Defence Force.

Mr. THOMAS KENNEDY asked the Secretary of State for War the number of members of the Chinese defence force that had died in China this year; the disabilities which were the cause of death; and the number of cases accepted as due to service in which the widows or other dependants had been granted pensions.—Commodore DOUGLAS KING replied: There have been 12 deaths in China among the British troops and two among the Indian troops, not forming part of the permanent establishment there. Eight of the cases were due to illness and the rest to accidents or wounds. In 11 of the 12 British cases there was no widow, and no claim has been received for dependant's pension. The twelfth case, which occurred at the end of June, is at present under consideration. I will ask my noble friend the Secretary of State for India, to ascertain whether any pension is being granted in either of the Indian cases and to communicate direct to the hon. Member the result of his inquiry.

Slum Clearances in Glasgow.

Mr. STEPHEN asked the Secretary of State for Scotland what steps had been taken by the Glasgow local authority in accordance with their statutory powers, to require the owners to make habitable the 1300 houses in the Camlachie Parliamentary division of Glasgow, which had been declared by the sanitary authority as unfit for human habitation, until new houses could be provided for the people concerned.—Mr. CHAMBERLAIN replied: The subject to which the hon. Member refers was considered by the consultative council at their meeting on July 21st. I am informed that they desire to give the matter further consideration before communicating to me their final views.

Plague Infection in the Port of London.

Mr. BENJAMIN SMITH asked the Minister of Health if he was aware that the ss. *Biela* and the ss. *Isapo*, now in the port of London with a cargo of grain, had been certified by the port sanitary authority to be suspect of containing vermin infected with bubonic plague; what steps he proposed to take to prevent the spread of infection; was he aware that three ships, the ss. *King Frederick*, the s. *Rossetti*, and the ss. *St. Holdsworth*, now in the port, were suspect of carrying vermin infected with bubonic plague; and what steps he proposed to take to prevent steamers from entering the river or docks of the port of London without examination, and to cause them, if discovered to be infected, to be placed under quarantine, and have all necessary precautions taken to prevent the carrying of the disease into the port.—Sir KINGSLEY WOOD replied: The answer to the first part of the question is in the affirmative, and to the third part in the negative. As regards the second part, as the hon. Member is aware, the port sanitary authority are responsible for the measures taken to prevent the spread of infection, and all necessary measures appear to have been taken in the case of the two ships mentioned in the first part of the question. As regards the fourth part, I am informed that all vessels from South American ports, bound for the port of London, are boarded at Gravesend, and that vessels from these ports carrying grain are at present receiving special attention. I think the hon. Member may rest assured that the port sanitary authority will take all necessary precautions to prevent the spread of infection.

Mr. B. SMITH asked whether the risk of infection did not reside, even after fumigation, in the carcase of the rat, which was sucked up in the suckers, distributed to various parts of London and ultimately sold as bread, mostly to poor people.

Sir K. WOOD: I hope that is not the case, but I can assure the hon. Member that precautions are being taken.

Mr. GOSLING asked if the hon. Member was satisfied, apart from what the port sanitary authority informed him, that he was safeguarding the people in the congested areas in the East End from this plague being carried ashore. There would be a great danger if it got into the port, and if it did so how was he going to stop it.

Sir K. WOOD: I can quite understand the natural apprehension arising in regard to the facts of this case, but I can assure the hon. Member that every step that is possible is being promptly, and I believe efficiently, taken.

Mr. SEXTON asked whether it was possible to insist that the grain should be carefully examined before it went into the bags in order to see that no dead bodies got mixed up with it during the discharge from the ship.

Sir K. WOOD: The hon. Member can rely upon it that his suggestion will be considered. I do not think that any unnecessary apprehension need arise, because I believe that effectual steps are being taken to deal with the situation.

Mr. BENJAMIN SMITH asked the President of the Board of Trade what precautionary measures were taken to prevent foreign countries shipping cereals, to which vermin infected with disease had access, on steamers loading for this country.—Sir KINGSLEY WOOD replied: In the case of foreign countries which have ratified the International Sanitary Convention of 1912, the port sanitary authorities of plague-infected ports are required to take effectual measures to prevent rats gaining access to ships.

Medical Examinations of Prisoners.

Mr. RHYS DAVIES asked the Home Secretary whether he was aware that, in accordance with a Home Office regulation, a person who was arrested for being drunk whilst in charge of a vehicle and who demanded to be examined by his own doctor, was not allowed to be so examined in private, the police insisting upon being present; and whether he would give instructions that in such cases the examination should be private, as was the practice in an interview between an accused person and his lawyer.—Sir WILLIAM JOYNSON-HICKS replied: I am aware that the general practice is as stated in the first part of the question and I think this practice is right. I cannot see how the interests of the prisoner can be prejudiced by the presence of a police officer, who may have to give evidence in court with regard to the examination. Interviews with solicitors are obviously on quite a different footing.

Ventilation of the London Tube Railways.

Mr. GILLETT asked the Minister of Transport whether his attention had been called to the recent prolonged stoppages in the London tubes and the discomfort inflicted on the passengers by the want of sufficient air; and whether he would take steps with a view to seeing what could be done to improve the ventilation.—Colonel WILFRID ASHLEY replied: I am in communication with the London Electric Company with regard to the question of the ventilation of tube railways.

WEDNESDAY, JULY 27TH.

Fishermen and Health Insurance.

Mr. ERNEST BROWN asked the Prime Minister whether an amending Bill for health insurance was in preparation; if so, whether fishermen were to be included in it; and if it would apply to Scotland.—Mr. CHAMBERLAIN (Minister of Health) replied: As soon as the consideration of the recommendations of the recent Royal Commission on National Health Insurance has been completed, it is hoped to introduce the necessary legislation, and the question of the compulsory insurance of share fishermen both in England and Scotland, in so far as they are not already included in the scheme, would be dealt with in such legislation.

Opium Cultivation in India.

Mr. THURTLE asked the Under Secretary of State for India whether he was now in receipt of the full report of the recent conference at Simla on opium cultivation in the Indian States; whether he would inform the House of the main decisions there arrived at; and whether he would

consider the question of publishing the proceedings of the conference in the form of a White Paper, in view of the public interest in the efforts being made to reduce the world production and consumption of opium for other than purely medical purposes.—Earl WINTERTON replied: My noble friend has received a report. The conference recommended that a committee should be formed to conduct a series of local inquiries, in which the States concerned would be associated, and suggested terms of reference covering the following questions: (*a*) the agricultural and financial aspects of the subject, including the possibility of replacing poppy by other crops and the effect of such substitution upon the prosperity of the States and their subjects; (*b*) a searching inquiry into the extent to which opium is consumed, the occasions on which and the purposes for which it is consumed, the manner in which it is prepared for consumption, and its physiological effects upon the consumer (the important question to what extent opium is administered to infants was not lost sight of); (*c*) the amount of the stocks of opium existing in the States and the best means of disposing of them; smuggling and remedies therefor; and, finally, the advisability and practicability of adopting the policy suggested by the Government of India—namely, the discontinuance of cultivation in the States, the purchase of opium by the States from the Government factory at Ghazipur at cost price and a gradual enhancement of the selling price of opium in the States, so as ultimately to equalise it with that prevailing in the adjoining British districts, and thereby to remove the incentive to smuggling into British India and reduce the average rate of consumption in the States. It is not proposed to publish a White Paper on the subject, but a copy of a communiqué issued in India regarding the proceedings is being placed in the library.

Death of a Woman Weaver at Arbroath.

Mr. JOHNSTON asked the Home Secretary whether he had had his attention drawn to the death of a woman weaver in an Arbroath factory; was he aware that this woman was 62 years of age and was engaged, along with another weaver, in lifting a piece of finished cloth weighing 115 lb., that the regulations in the woollen trades forbade women lifting cloth pieces weighing over 50 lb., and that the jury at the inquiry under the Fatal Accidents Act had drawn attention to the dangers of heavy weight-lifting by women; and what steps, if any, he proposed to take.—Captain HACKING (Under Secretary for the Home Office) replied: A report on this case has been called for and when it is received the Home Secretary will go carefully into the matter and communicate the result to the hon. Member.

Lunacy Act Regulations.

Mr. GOSLING asked the Minister of Health if he was aware that the Cobb Committee recommended that Section 79 of the Lunacy Act should be posted up in the rooms where friends came to visit pauper patients; and why this had not been done, so that friends, as well as relatives, might be made aware of the rights conferred on them by the statute.—Mr. CHAMBERLAIN replied: In the opinion of the Board of Control there are serious objections to a general requirement that this section should be posted up in waiting-rooms. The revised rules of the Board of Control, dated Jan. 7th, 1925, provide that:—

"The managers of every institution for lunatics shall, on the admission of every pauper lunatic to an institution for lunatics, send a notice to all persons, whose names appear as relatives or friends of the patients on the statement of particulars accompanying a reception order, as to the times and conditions of visitation; and in such notice shall be embodied the substance of Section 79 of the Lunacy Act, 1890."

THURSDAY, JULY 28TH.

Street Accidents in London.

Mr. DAY asked the Home Secretary the number of accidents, fatal and otherwise, that had taken place in the streets of the metropolitan police district for the month of June, 1927.—Sir W. JOYNSON-HICKS replied: The number of accidents known to the police during the month of June, 1927, is as follows:—

Fatal accidents	92
Non-fatal accidents involving personal injury	4500
Accidents involving damage to property only	5699
Total number of accidents known to the police	10,291

As a result of these accidents the total number of persons killed was 92, and injured 4863.

Surgical and Medical Treatment of Prisoners.

Mr. HAYES asked the Home Secretary the number of persons who were removed from prisons to outside hospitals in order that operations might be performed during the year 1926, and the number of cases of childbirth, if any, that took place inside prisons, including Broadmoor, during the year 1926.—Sir WILLIAM JOYNSON-HICKS replied: Ninety-eight persons were removed from prison during 1926 under Section 17 (6) of the Criminal Justice Administration Act, 1914, for surgical or medical treatment which could not be given in prison. The number of cases of childbirth in prison (including two in the Aylesbury Borstal Institution) during the same year was 18. The corresponding figures for Broadmoor are none and one.

Mr. HAYES: Would an amendment of the law be necessary in order that cases of this character might be treated outside prison?

Sir W. JOYNSON-HICKS: If it were compulsory, yes, an amendment of the law would be necessary. There is always a prerogative which in certain cases is exercised, and in certain cases is not exercised.

Mr. DAY: How many of these 98 people were on parole and how many in custody during the operations?

Sir W. JOYNSON-HICKS: I cannot say without notice. There is provision under the Act for removal to hospital for the purpose of surgical or medical treatment which cannot be given in prison, and there are arrangements made for the persons concerned to go back to prison when the operation is over.

Mr. HAYES asked the Secretary of State for Scotland the number of persons who were removed from prisons to outside hospitals in order that operations might be performed during the year 1926; and the number of cases of childbirth, if any, that took place inside prisons during the year 1926.—Sir JOHN GILMOUR replied: Thirty-one prisoners were removed from Scottish prisons to outside hospitals during the year 1926 for the purpose of undergoing operations. No births took place in Scottish prisons in 1926.

Opium Cultivation in British India.

Mr. BARKER asked the Under Secretary of State for India the amount and value of opium manufactured by the Government of India and sold for exportation each year for the last three years; and whether any part of the opium sold for exportation under the authority of the Government of India was manufactured in the Indian States.—Earl WINTERTON replied: The following table shows the amount and value of opium manufactured by the Government of India sold for exportation in the last three years for which figures are available:—

	Chests of 140 lb. sold.	Amount realised in Rs.
1923	7954	3,13,34,650
1924	7379	2,80,06,775
1925	6119	2,54,35,350

The answer to the second part of the question is in the negative.

Population Statistics.

Mr. BROMLEY asked the Minister of Health the male and female population of England and Wales for 1913, 1919, and 1921 to 1927, respectively.—Mr. CHAMBERLAIN replied: The following is the information asked for:—

England and Wales.

Year.	Population.		Year.	Population.	
	Males.	Females.		Males.	Females.
1913	17,687,000	18,887,000	1924	18,545,000	20,201,000
1919	17,803,000	19,559,000	1925	18,602,000	20,288,000
1921*	18,075,239	19,811,460	1926	18,698,000	20,369,000
1922	18,225,000	19,933,000	1927	18,763,000	20,440,000
1923	18,342,000	20,061,000			

* Census.

With the exception of those for the year 1921, which are Census figures, the above populations are mid-year estimates. Those given for 1927 should be regarded as provisional.

Appointments.

MATHER, A., M.B., Ch.B. Liverp., D.P.H., Assistant Medical Officer of Health for the Maternity and Child Welfare Department of the Warrington Corporation.

MILLER, H., M.B., Ch.B. Glasg., and MUIRHEAD, A. J., M.B., Ch.B. Edin., District Medical Officers (Medical Referees) Scottish Board of Health.

TORRENS, D. F., M.B., B.Ch. Dub., Certifying Surgeon under the Factory and Workshop Acts for Market Rasen District (Lincoln).

WELLS, NESTA H., M.B., Ch.B. Manch., Medical Officer to the Manchester Watch Committee for the Examination of Women Suspects.

West Bromwich and District Hospital: CLOAKE, P. C., M.D., B.S. Lond., D.P.H., D.P.M. Camb., WILSON, M.B., B.S. Lond., Honorary Physicians; LEATHER, J., M.B., B.S. Camb., F.R.C.S. Edin., Honorary Orthopædic Surgeon; GILHESPY, F. B., F.R.F.P.S. Glasg., M.R.C.S., L.R.C.P. Lond., Honorary Ear, Nose and Throat Surgeon,

Vacancies.

The Chief Inspector of Factories announces vacant appointments for Certifying Factory Surgeons at Towcester (Northamptonshire), and Crewkerne (Somersetshire).

Births, Marriages, and Deaths.

BIRTHS.

MARTIN.—On July 26th, the wife of James Purdon Martin, M.D., Corringham-road, N.W., of a son.
MOOR.—On July 28th, at Irton, Westgate-on-Sea, the wife of Dr. Frewen Moor, of a son.

MARRIAGES.

BANES—PERRY.—On July 6th, at St. Clement Danes, Strand, Charles Douglas Banes, M.B., B.S., to Beatrice Mary Perry.
MACDONALD—STUART.—On July 27th, at the Parish Church, Stroud, Alexander John Macdonald, R.E., to Stella Constance Christian Stuart, M.R.C.S., L.R.C.P., daughter of Lt.-Col. and Mrs. D. F. Stuart.

DEATHS.

CLIFFORD.—On July 26th, at a nursing home at Bickley, Kent, Maurice Clifford, M.R.C.S., L.R.C.P., aged 76.
DONKIN.—On July 26th, at Hyde Park-street, W., Sir (Horatio) Bryan Donkin, M.D., F.R.C.P., Consulting Physician to the Westminster Hospital, in his 83rd year.
EDWARDS.—On July 18th, at his residence, 11, Hawkwood-road, Albert Davies Edwards, M.B., B.S. Lond., B.Sc., D.P.H., Medical Officer of Health, Bournemouth, in his 48th year.
FOX.—On July 23rd, suddenly, at Arundel-gardens, W., Dr. Francis Fox, aged 86.
HIRSCH.—On July 28th, at the Temperance Hospital, Dr. Charles Hirsch, of Old Park House, Ifield, Sussex.
LAWSON.—On July 28th, at the London Hospital, Henry Dillon Lawson, L.R.C.P., M.R.C.S., elder son of the late Henry A. Lawson, L.R.C.P. & S. Edin.
VINRACE.—On July 26th, Felix Coulson Vinrace, M.D., F.R.C.S. Eng., of Birmingham, and Moseley.

*N.B.—A fee of 7*s.* 6*d.* is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Notes, Comments, and Abstracts.

THE BIRTH CONTROL HANDBILLS OF 1823.

BY NORMAN E. HIMES, M.A., B.Sc.,
SOMETIME ROBERT TREAT PAINE FELLOW IN SOCIAL ETHICS, HARVARD UNIVERSITY; FELLOW SOCIAL SCIENCE RESEARCH COUNCIL, U.S.A.

IN view of the interest taken by THE LANCET in the discussion of the medical aspects of birth control (see the leading article in the issue of May 28th, 1927, and the able critical review by Dr. C. P. Blacker of a recent book on the subject, which review was published in the same number); in view of the increasing attention which has been given by THE LANCET and other medical journals to the technique of contraception and its history; in view of the opinion, which is still very widespread, that the organised birth control movement is of recent origin, it might be profitable to inquire into the nature of an attempt over a hundred years ago to give the general populace, and especially the working classes, access to knowledge on what would now be called birth control—this without the coöperation, for the most part, of the medical profession.

The opinion is still very general that birth control propaganda, so-called, is a social phenomenon which had its beginnings in the last quarter of the nineteenth century. Nothing could be further from the facts. Although it is true that the popular advocacy of birth control, especially on social and economic grounds, was reinforced by the prosecution of Charles Bradlaugh and Annie Besant in 1877 for the publication of Dr. Charles Knowlton's "The Fruits of Philosophy,"[1] it is clear that the decade of the 1820's produced an agitation of singular interest not only to the physician but to the economist and sociologist. Nor did the public demand for information become quiescent between 1830 and 1877; less noisy it did become after the death of Malthus in 1834; but the passing of the figure around whom the population storm raged, the widening of the suffrage and the passage of the New Poor Law merely poured oil on the troubled sea of social difficulties; the propaganda continued, and the distribution of birth control tracts went quietly on.

We shall concern ourselves here with one phase only of the agitation of the 1820's. That phase is the handbill propaganda which seems to have been initiated by Francis Place[2]—by trade a tailor, by avocation a schoolmaster to statesmen. Place, incidentally, was united by the bonds of friendship, and, to a limited extent, by the cords of a common feeling with Thomas Wakley, the medical reformer who founded, and who for a number of years edited, THE LANCET.[3] It should be observed that Place's generalship in supervising the distribution of the broadsheets about to be described was but a small part of an organised, concerted attempt to bring a contraceptive technique to the working classes without extensive aid from the medical profession. We confine ourselves here not simply to the handbills, but limit ourselves to reproducing them and making certain observations on their social, economic and medical implications.

The question of the origin of the method recommended—the moistened sponge—the question as to whether it was introduced from France or independently hit upon here need not detain us. But it may be mentioned in passing that although Place started the rumour that Robert Owen, New Lanark philanthropist, introduced the new preventive check from France[4]; although his statement was repeated by T. J. Wooler, editor of a radical newspaper called the *Black Dwarf*[5]; and although the Owen "anecedote" was reiterated in two separate publications of Richard Carlile[6] (Place's birth control disciple), conclusive evidence has since come to light which would seem to demonstrate that if the sponge, as a contraceptive technique, had a French origin it was *not* introduced into England by Robert Owen.

James Mill, the eminent political economist, had no sooner broached the subject in his Colony article in the Supplement to the *Encyclopedia Britannica*[7] (1818) than the pros and cons of contraception seem to have been discussed in the inner circle of the Benthamite group. Place began his public advocacy of birth control in his "Illustrations and Proofs of the Principle of Population"[8] (1822) but no mention was there made of methods.

It was not until the summer of 1823 that Place initiated a distribution of handbills among the general populace.[9] Copies of these bills are preserved in what is known as the Place Collection at the British Museum.[10] They exist in two forms, printed and manuscript. The three printed forms of the handbills are addressed respectively "To the

Married of Both Sexes," [11] "To the Married of Both Sexes in Genteel Life," [12] and "To the Married of Both Sexes of the Working People." [13] The first two were neatly printed on a single sheet about 5 by 9 in., while the third was a four-page pamphlet approximately 3 by 5¾ in. Still another draft, addressed "to the mature reader of both sexes," [14] is preserved in manuscript on both sides of a single sheet 6½ by 7½ in. The handwriting in this manuscript draft is not that of Francis Place.

Four Handbills.

The handbills read as follows :—

I.

TO THE MARRIED OF BOTH SEXES.

In the present state of society, a great number of persons are compelled to make an appearance, and to live in a stile, which consumes all their incomes, leaving nothing, or next to nothing, as a provision for their children. To such persons a great number of children, is a never failing source of discomfort and apprehension ; of a state of bodily, mental, and pecuniary vexation and suffering, from which there is no escape. This state of things pervades, to a very great extent, that respectable class of society called genteel. To those whose incomes depend on some particular exertion, which cannot be remitted, these distressing circumstances are from various causes, greatly increased. To those who constitute the great mass of the community, whose daily bread is alone procured by daily labour, a large family is almost always the cause of ruin, both of parents and children ; reducing the parents to cheerless, hopeless and irremediable poverty ; depriving the children of those physical, moral, and mental helps which are necessary to enable them to live in comfort, and turning them out at an early age to prey upon the world, or to become the world's prey.

For these general reasons, cognizable by every body, it is of the greatest possible importance that married people should be informed of the methods used to prevent such tremendous evils.

If methods can be pointed out by which all the enjoyments of wedded life may be partaken of without the apprehension of TOO LARGE *a family*, and all its bitter consequences, he surely who points them out, must be a benefactor of mankind. Such at any rate are the motives which govern the writer of this address.

The means of prevention are simple, harmless, and might, but for false delicacy, have been communicated generally. They have long been practised in several parts of the Continent, and experience has proved, that the greatest possible benefits have resulted ; the people in those parts, being in all respects better off, better instructed, more cheerful, and more independent, than those in other parts where the practices have not prevailed to a sufficient extent.

The methods are two, of which the one to be first mentioned seems most likely to succeed in this country as it depends upon the female. It has been successfully resorted to by some of our most eminent physicians, and is confidently recommended by first-rate Accoucheurs, in cases where pregnancy has been found injurious to the health of delicate women. It consists in a piece of sponge, about an inch square, being placed in the vagina previous to coition, and afterwards withdrawn by means of a double twisted thread, or bobbin, attached to it. No injurious consequences can in any way result from its use, neither does it diminish the enjoyment of either party. The sponge should, as a matter of preference, be used rather damp, and when convenient a little warm. It is almost superfluous to add that there may be more pieces than one, and that they should be washed after being used.

The other method resorted to, when from carelessness or other causes the sponge is not at hand, is for the husband to withdraw, previous to emission, so that none of the semen may enter the vagina of his wife. But a little practice and care in the use of the sponge will render all other precautions unnecessary.

II.

TO THE MARRIED OF BOTH SEXES IN GENTEEL LIFE.

Among the many sufferings of married women, as mothers, there are two cases which command the utmost sympathy and commiseration.

The first arises from constitutional peculiarities, or weaknesses.

The second from mal-conformation of the bones of the Pelvis.

Besides these two cases, there is a third case applicable to both sexes : namely, the consequences of having more children than the income of the parents enables them to maintain and educate in a desirable manner.

The first named case produces miscarriages, and brings on a state of existence scarcely endurable. It has caused thousands of respectable women to linger on in pain and apprehension, till at length, death has put an end to their almost inconceivable sufferings.

The second case is always attended with immediate risk of life. Pregnancy never terminates without intense suffering, seldom without the death of the child, frequently with the death of the mother, and sometimes with the death of both mother and child.

The third case is by far the most common, and the most open to general observation. In the middle ranks, the most virtuous and praiseworthy efforts are perpetually made to keep up the respectability of the family ; but a continual increase of children gradually yet certainly renders every effort to prevent degradation unavailing, it paralizes by rendering hopeless all exertion, and the family sinks into poverty and despair. Thus is engendered and perpetuated a hideous mass of misery.

The knowledge of what awaits them deters vast numbers of young men from marrying and causes them to spend the best portion of their lives in a state of debauchery, utterly incompatible with the honourable and honest feelings which should be the characteristic of young men. The treachery, duplicity, and hypocrisy, they use towards their friends and the unfortunate victims of their seductions, while they devote a large number of females to the most dreadful of all states which human beings can endure extinguishes in them to a very great extent, all manly, upright notions ; and qualifies them to as great an extent, for the commission of acts which but for these vile practices they would abhor, and thus to an enormous extent is the whole community injured.

Marriage in early life, is the only truly happy state, and if the evil consequences of too large a family did not deter them all men would marry while young, and thus would many lamentable evils be removed from society.

A simple, effectual, and safe means of accomplishing these desirable results has long been known, and to a considerable extent practised in some places. But until lately has been but little known in this country. Accoucheurs of the first respectability and surgeons of great eminence have in some peculiar cases recommended it. Within the last two years, a more extensive knowledge of the process has prevailed and its practice has been more extensively adopted. It is now made public for the benefit of every body. A piece of soft sponge about the size of a small ball attached to a very narrow ribbon and slightly moistened (when convenient) is introduced previous to sexual intercourse, and is afterwards withdrawn, and thus by an easy, simple, cleanly and not indelicate method, no ways injurious to health, not only may much unhappiness and many miseries be prevented, but benefits to an incalculable amount be conferred on society.

III.

TO THE MARRIED OF BOTH SEXES OF THE WORKING PEOPLE.

This paper is addressed to the reasonable and considerate among you, the most numerous and most useful class of society.

It is not intended to produce vice and debauchery, but to destroy vice, and put an end to debauchery.

It is a great truth, often told and never denied, that when there are too many working people in any trade or manufacture they are worse paid than they ought to be paid, and are compelled to work more hours than they ought to work.

When the number of working people in any trade or manufacture, has for some years been too great, wages are reduced very low, and the working people become little better than slaves.

When wages have thus been reduced to a very small sum working people can not longer maintain their children as a good and respectable people wish to maintain their children but are compelled to neglect them ;—to send them to different employments ;—to Mills and Manufactories, at a very early age.

The misery of these poor children cannot be described, and need not be described to you who witness them and deplore them every day of your lives.

Many indeed among you are compelled for a bare subsistence to labour incessantly from the moment you rise in the morning to the moment you lie down again at night, without even the hope of ever being better off.

The sickness of yourselves and your children, the privation and pain and premature death of those you love but cannot cherish as you wish, need only be alluded to. You know all these evils too well.

And, what, you will ask is the remedy ?

How are we to avoid these miseries ?

The answer is short and plain : the means are easy. Do as other people, do, to avoid having more children than they wish to have, and can easily maintain.

What is done by other people is this. A piece of soft sponge is tied by a bobbin or penny ribbon, and inserted just before the sexual intercourse takes place, and is withdrawn again as soon as it has taken place. Many tie a piece of sponge to each end of the ribbon, and they take care not to use the same sponge again until it has been washed.

If the sponge be large enough, that is ; as large as a great walnut, or a small apple, it will prevent conception, and thus without diminishing the pleasures of married life, or doing the least injury to the health of the most delicate woman, both the woman and her husband will be saved from all the misery which having too many children produces.

By limiting the number of children, the wages both of children and of grown up persons will rise ; the hours of working will be no more than they ought to be ; you will have some time for recreation, some means of enjoying yourselves rational, some means as well as some time for your own and your children's moral and religious instruction.

At present every respectable mother trembles for the fate of her daughters as they grow up. Debauchery is always feared. This fear makes many good mothers unhappy. The evil which it comes makes them miserable.

And why is there so much debauchery ? Why such sad consequences ?

Why ? But, because many young men, who fear the consequences which a large family produces, turn to debauchery and destroy their own happiness as well as the happiness of the unfortunate girls with whom they connect themselves.

Other young men, whose moral and religious feelings deter them from this vicious course, marry early and produce large families, which they are utterly unable to maintain. These are the causes of the wretchedness which afflicts you.

But when it has become the custom here as elsewhere, to limit the number of children, so that none need have more than they wish to have, no man will fear to take a wife, all will be married while young—debauchery will diminish—while good moral and religious duties will be promoted.

You cannot fail to see that this address is intended solely for your good. It is quite impossible that those who address you can receive any benefit from it, beyond the satisfaction which every benevolent person, every true christian, must feel at seeing you comfortable, healthy, and happy.

IV.

TO THE MATURE READER OF BOTH SEXES.

The object of this handbill is not to encourage vice and lebauchery: but to prevent misery: not to destroy children nce conceived, as many, and even married women do, to the lestruction of their healths; but to prevent improper and ndesired conceptions, where sexual intercourse is desirable, nd wholesome, and lawful.

To accomplish this important object, an object more important han any other that affects either the society or an individual, ome respectable persons in the metropolis of this country, of oth sexes, among whom are included many medical men of he first rank, have enquired after a means which is here nfolded.

All animal procreation is the result of seminal contact etween the sexes. With mankind and healthy married people, exual intercourse is as unavoidable, as it is wholesome and irtuous. But it is by no means desirable, it is indeed, a ontinued torture, that a married woman should be incessantly reeding or bringing forth children, often unhealthy, and born ith a certainty of death in infancy and nothing but the patients f pain: as often born where there are not the means of whole-ome support: and, what is still worse, where the mother is of a elicate frame, and never can produce healthy children, conception s to her nothing but torture, without even the most distant rospect of pleasure or utility. Every reader will be able to ook round and see an abundance of such of each of the cases ere stated.

The remedy then is one, and only one, and that most simple, ithout even a shade of impropriety—conceptions should be revented by the female, by absorbing the semen of the male ith a small bit of moistened spunge, or with any other bsorbing substance, such as lint, fine wool, cotton, flax, or hat may be at hand, instead of allowing that semen to be bsorbed by those vessels which lead to conceptions. Once ractised, all idea of indelicacy or inconvenience will vanish. he practise has long and wisely existed on the continent of urope, and every where the best effects arise from it. It is lone applicable to married and to virtuous people, and to healthy nd pure intercourse.

Comments on the Handbills.

Interesting comparisons may be made of these handbills. irst, as to methods recommended: the form first roduced here (which was the first actually issued) ientions *coitus interruptus* as well as the sponge; the second nd third refer only to the latter, while the manuscript raft recommends, as an alternative to the "moistened punge," a tampon of "lint, fine wool, cotton, flax, or what ay be at hand." As might be expected from such an arly attempt, a physiological naivité pervades the bills. Ve are informed in the first that "the use of the sponge will nder all other precautions unnecessary"; the third nforms us that "the means of preventing conception re easy." There is no suggestion in this or any of the ther literature of the period that the methods proposed are ot "fool-proof." In the bill addressed "To the Married of oth Sexes in Genteel Life" (second form), we have an rly mention, possibly the first mention, of two medical dications for contraception—contracted pelvic condition nd constitutional weakness. I say it is *possible* that this the first mention of these medical indications for ntraception; I think it is quite *likely* that they have no ntecedents. It has, of course, been known for centuries at a narrow pelvis increased the dangers of parturition, t the handbill referred to seems to contain the first reference these or other conditions as medical indications for *ntraception.*

From the social and economic point of view the case for ntraception is much weaker in the first bill than in the vo succeeding ones. The second form suggests that ntraception might be used to advantage to maintain one's ation in life, or in the circumstance of a low family income. oreover, it is not altogether unworthy of note that these *ay be*—no one can say conclusively that they *are*—among e chief reasons why contraception is being so widely plied today. The fact that more or less effective methods e at hand together with the realisation, first observed in e economic writings of the ancients and early Hebrews, at human wants expand faster than incomes has obably had much influence upon the readiness with which ch practices have been adopted. In the bills which re issued later we have the economic case for birth ntrol set forth more clearly. In fact, the chief arguments opounded for birth control in this period were economic. ntral among them were deductions from the wages-fund eory which was supposed to mete out to the labourers eir just wages in the stern, harsh ratio of numbers to pital. Even if the wages-fund be considered Place's vourite foundation for the preventive check, he fortunately ttressed his appeal in his authentic writings with other edical, social, and economic considerations. He did not glect health conditions and the intangible but nevertheless portant factor of marital adjustment. There is a ggestion of the wages-fund argument in the handbill dress to the "working people" but, in addition, it is ged that the check on large families will raise wages by rtailing the supply of labour; that it will shorten hours resumably by increasing labours' bargaining power), and that it will open up to the working classes new possibilities for leisure with all the social consequences which might reasonably be expected to result from the profitable employment of such leisure. It is in both the later drafts that we have one of the earliest uses of the argument of birth controllers that the paramount objection to the Malthusian doctrine of "moral restraint" is that, other things being equal, irregular unions are likely to be more frequent in a society where marriages are, in general, late than in a society where there is widespread early marriage with a consequent adoption of contraception. Since it is not our purpose to examine the validity of any of these observations, we pass on to point out that the handbill addressed "To the Married of Both Sexes of the Working People" suggests an argument heard much in America, but not so frequently in this country, that large families are a cause of child labour. It is probably true that large families and child labour tend to go together; but whether the large families cause, or contribute to cause, child labour, or whether in some cases children are raised partly with the idea that their labour will be valuable is a debatable point. My own opinion is that large families are a contributory, causative factor in child labour and its continuation. So much for certain social observations which might be made on the handbills.

Although the fourth, manuscript of a handbill addressed "to the mature reader of both sexes" was never printed and distributed [15] it contains an interesting variation of statement which throws light on the relation of the medical profession to this early propaganda. It advises us that "some respectable persons in the metropolis of this country, of both sexes, among whom are included many medical men of the first rank, have inquired after a means which is here unfolded." It is true that this is the only straightforward statement in the literature of the period which *directly* associates any medical men with the *initiation or conduct* of the propaganda; but it is also interesting to note that Place sought medical advice and opinion on the subject of birth control. Unlike some modern birth control propagandists Francis Place had a research attitude; he had an Aristotelian penchant for fact collecting. Hence we find him writing to his friend Maclaren, "I have taken pains in my enquiries on this subject . . . amongst surgical and medical as [well as] amongst intelligent elderly women, and especially with two respectably clever women who are or were matrons at public lying-in hospitals." [16] Thus although there is no *record* of physicians having taken any active part in the *propaganda*, they seem to have had an indirect hand in fostering this reform. Indeed, speaking of the method proposed, the second handbill avers that "Accoucheurs of the first respectability and surgeons of great eminence have in some peculiar cases recommended it," while a similar statement appears in the first handbill.

The exact extent of the distribution of these bills is unknown. While it is easy to exaggerate their influence and the extent of their dissemination, it is clear that they were broadcasted in the provinces as well as in London. Judging by manuscript drafts of letters preserved by Place, he was instrumental in sending to Manchester, care of Mr. Edward Taylor, editor of the *Manchester Guardian*, a parcel of handbills with a letter requesting that he forward them to a Mrs. Fildes whose efforts in behalf of the working classes were well known. A note accompanied the package asking Mrs. Fildes to distribute them; highly offended, she urged Sir Henry Gifford, the Attorney-General, to prosecute but he failed to do so. Another letter of objection from Mrs. Fildes led to their publication, however, in the *Black Dwarf*, which was hostile to the distribution. Copies, nevertheless, seem to have been distributed in Manchester, if not by Mrs. Fildes, then through the instrumentality of William Longson, a journeyman weaver for whom Place at that time had done essential service. Place sent Longson handbills with a letter urging him to use them to lessen the burden of pauperism in the community. One gathers from certain mid-century Manchester newspapers recalling the early propaganda that the handbills received considerable circulation in that community. They were distributed among the Spitalfield weavers. The industrial districts were not immune to them.[17] They were sent to gentlemen who gave evidence before a Parliamentary committee on labourers' wages.[18]

This is not the place to record the "scandals" and exposures which followed, but it needs to be observed that it was not long before Place was publicly dubbed "the master spring that moves the whole infernal machine." [19] Indeed, such he was. But since we have confined ourselves here to one aspect only of the "diabolical handbills," which was, in turn, only a part of this attempt to get contraceptive knowledge to the working classes, space does not permit us to show the extent to which Place inspired and conducted discussions of the subject in working men's newspapers, how he brought several religious and political reformers to his point of view, and how, by his conversion of Richard Carlile, he set in motion that whole chain of forces which has been mainly responsible for the spread among the general populace,

both in England and in America, of a knowledge of contraception. But we should like to point out, in concluding, that it is to no small degree a consequence of the social forces released through Place, and reinforced by his disciples in England and America—a chain of events clearly traceable—that we owe our present and past decline in the birth-rate in both countries, a decline which constitutes one of the most revolutionary social changes of modern times.

References.

1. The Fruits of Philosophy; or, the private companion of young married people by Charles Knowlton, M.D., was the first book on birth control ever written by an American physician and the second American treatise on the subject—Robert Dale Owen's Moral Physiology; or, a brief and plain treatise on the population question (N.Y. 1830) having been the first. Knowlton's little book (it was 32 mo.) was originally published anonymously in N.Y. in January, 1832, a second edition with additions appearing in Boston in 1833. It was reprinted in England about 1834 and sold undisturbed for 40 years in various editions before the sensational trial of the 'seventies. Bradlaugh and Besant changed the title of their edition (Freethought Publishing Co.) to the following: The Fruits of Philosophy. An Essay on the Population Question.
2. The best biography is Graham Wallas's The Life of Francis Place. The Dictionary of National Biography has a brief but admirable account by the same author.

6. Republican, vol. xi., No. 18, p. 556 (May 6th, 1825); cf. also Every Woman's Book; or, What is Love? London: R. Carlile, 1826, p. 24, fourth edition. No. 18 of the Republican was entirely devoted to Richard Carlile's essay on What is Love? except for a few pages. It is the first treatise exclusively devoted to a medical, social, and economic discussion of birth control in the English language and is more or less the parent of the chief birth control tracts of the nineteenth century. The essay was republished in somewhat altered form in February, 1826, as Every Woman's Book; or, What is Love? of which but one authentic copy is extant, to my knowledge, in any of the chief repositories in England or America. Francis Place, as is erroneously stated by Dr. Marie Stopes (Contraception: its Theory, History and Practice, p. 269), was not the author of What is Love?; nor was Place the author of Every Woman's Book. Place, far from being its author, actually did his utmost to dissuade Carlile from publishing it. Place may have disapproved of the vulgarity which characterised the publication, but it is more probable that he felt Carlile might wisely keep out of print until he had mastered the subject.
7. Place arranged for reprinting it as a tract; it was later bound with the reprints of James Mills' other contributions to the encyclopædia.

Except for stray volumes it comprises approximately 250 large tomes. Citations from volumes at Hendon are herein referred to as Hendon, followed by the volume and page numbers.
11. Hendon, vol. lxi., Part II., p. 43.
12. Loc. cit. 13. Ibid., p. 42.
14. Hendon, vol. lxviii., p. 103. At the botton of the second page of this manuscript are the words "Benjamin Aimé" in Place's handwriting and familiar ink, as if to indicate authorship by his customary method. Field, in the only accurate and authentic account of this propaganda (cited above; cf. footnote 9) observed that the Triennial Directory (London, 1822) listed Benjamin Aime (without the accent) as a musical instrument-maker. The name, however, occurs so frequently in Place's diary *with* the accent that it would seem either: (1) that the directory was inaccurate, or (2) that Place had reference to someone other than the instrument-maker. One Aimé frequently called upon Place with French books, especially at the time when Carlile was seeking Place's advice on Every Woman's Book.
15. One or more of the handbills were printed in several journals of the time, but in no case did the manuscript form ever appear. In fact, Carlile, in May, 1825, stated that he had seen only two forms. (Republican, vol. xi., p. 561.)
16. Place to Maclaren, Hendon, vol. lxii., p. 163. Richard Carlile said he "studied anatomy in the regular way" (Old Monthly Magazine, May, 1835). The evidence of Place's fact-collecting propensities are the 250 tomes in the British Museum. His "Notes on Surgery and Medicine" are to be found in Add. MSS. 27, 828 (vol. iv.), section 5.
17. See the letter of William Smith of Bolton to Place in Hendon, vol. lxi., Part II., p. 60, quoted in part by Field, ibid., p. 225. Carlile said that they circulated by thousands in the populous districts of the North. (Republican, vol. xi., p. 555.)

SUBSTITUTES FOR WINDOW GLASS.

APART from the beneficial effects of the sun's rays in actu disease the prophylactic use of sunlight becomes increasing important as towns expand and open spaces disappe The difficulty of providing buildings with windows that w not seriously cut down the shorter rays of the sun's spectru has now been tackled both in a scientific and commerc manner, with the result that for glazing windows materi are now available which are satisfactorily transparent r only to the visible but to the ultra-violet rays of sunligh

A report published in the *Journal of the American Medi Association* of May 14th, under the ægis of the Associatio Council of Physical Therapy, may be taken as a scienti assay of the substitutes for window glass available in t United States. The report deals with two actual glas (Vitaglass and Corning glass) and two glass substitu (Celoglass and Flexoglass). Of Vitaglass there are two kin clear and "cathedral" (the latter being a merely transluce form), and these varieties are presumably the same as th sold in this country. Corning glass transmits 75 per cent. the shortest rays of the solar spectrum (3000 A.U.), whi Vitaglass transmits 30 per cent. of the same wave-leng ordinary glass being quite opaque to this part of spectrum. Since it is the shorter wave-length rays that ha the greatest biological value, both these special glasses be valuable where the object is to get the full physiologi value of sunlight.

Flexoglass is described as thin, fairly loosely woven cl impregnated with a paraffin-like substance; Celoglass fine wire mesh supporting a celluloidinous substance, an apparently similar to the material sold in this country un the name of Windolite. Both these substitutes allov certain proportion of the actinic rays to pass, but as t are of variable thickness and diffusing power, it is impossi to record their transmission spectra with the same accur as that of a true glass.

In view of the well-established fact that it is the sho ultra-violet rays of sunlight that make heliotherapy valu in the prophylaxis and cure of rickets, it seems ha necessary to have tested the value of these glass substit biologically. The report, however, furnishes the confirma evidence that when these materials were arranged as scr in front of experimental cages, fowls so screened v protected from "leg weakness," the avian equivalen rickets. Corning glass was not tested in this way, bu view of its marked transparency to the ultra-violet ray about 3000 A.U. it may be confidently supposed that it i least as efficient as the other materials tested.

FOAMING AT THE MOUTH.

CORRESPONDENTS have sent us "A Talk on Fraud Bread," by Mr. Ellis Barker, and have asked us if observer is correct in saying: "Unfortunately, most do know nothing or next to nothing about dietetics and themselves die like flies from diseases consequent faulty nutrition." Mr. Ellis Barker states in the sentence to this quotation that he has already shown things to be true, from which it must be concluded he has had access to vital statistics with which other unfamiliar, though it need not be assumed that he understood them. The best advice that medical men give to those who are perturbed by such articles is they should insist on being informed on what basis of or on what accepted doctrines of chemistry whol accusations of ignorance and fraud are being made; should ask to be supplied with the names and address the chemical manufacturers "who are spreading dis suffering, and death among millions," and the names burial-places of the doctors who have died in epi proportions of nutritional diseases. Some names shou forthcoming both from a class which can slay by mi and a profession which is dying like flies.

INFECTIOUS DISEASE IN ENGLAND AND W DURING THE WEEK ENDED JULY 23RD, 19

Notifications.—The following cases of infec disease were notified during the week:—Small 195 (last week 156); scarlet fever, 1575; diphth 852; enteric fever, 132; pneumonia, 612; puer fever, 36; puerperal pyrexia, 98; cerebro-s fever, 7; acute poliomyelitis, 10; acute encephalitis, 1; encephalitis lethargica, 35; dysen 6; ophthalmia neonatorum, 95. There were no ca cholera, plague, or typhus fever noified during the

Deaths.—In the aggregate of great towns, incl London, there was no death from small-pox, from enteric fever, 29 (3) from measles, 3 (3) scarlet fever, 24 (4) from whooping-cough, 3 from diphtheria, 38 (7) from diarrhœa and ent under two years, and 25 (4) from influenza. figures in parentheses are those for London itself

Arris and Gale Lecture

ON THE

TOXÆMIA OF ACUTE INTESTINAL OBSTRUCTION.

Delivered at the Royal College of Surgeons of England on March 18th, 1927,

BY R. ST. LEGER BROCKMAN, M.CHIR. CAMB., F.R.C.S. ENG.,

ASSISTANT SURGEON, SHEFFIELD ROYAL INFIRMARY; LATE HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS.

MODERN surgery has reached a high pinnacle of fame and perfection, and whilst its achievements in many branches may justify a large measure of pride and of hope, the almost stationary rate of mortality in acute obstruction wrings from all of us a confession of the failure of present modes of treatment, and further it forces an acknowledgment of the fallacy of the basic ideas from which these methods spring. In the struggle to right the wrong in the bodies of his fellow-men the operating surgeon depends for his increasing knowledge and inspiration upon two main sources of supply; the lessons of clinical work as judged by results and the light gained from experiments on animals. Confronted by undoubted failure it behoves us at the outset carefully to examine the use made of these founts of learning and thereby to see if possible where and why we have gone astray.

The forward march of operative technique has been so astounding and so rapid that our perspective of what surgery really is has been thrown out of alignment; and our judgment of what it can in truth perform has become somewhat biased. It can do and has done so much that it has rather been expected to do all. On analysis surgery is of the mechanical *mechanical*, and its lasting kingdom can only be in those realms of disease which have an origin fundamentally mechanic. It is true that the cause of acute obstruction is of this nature, but the cause of ileus is not, since this can and does appear in peritonitis, in uræmia, and in other pathological states devoid of any mechanical interference with the proper working of physiological processes. Organic obstruction is one thing which must ever be submitted to manual repair, but ileus is always ileus; it is always paralytic in nature, and has a much more fundamental basis of being, and in its cure surgery can, I believe, have no real part. It is for this reason that enterostomy, enteroanastomosis, jejunostomy, and the like procedures have so signally failed us in our efforts to cope with this condition. From a realisation of this impotence there goes up the cry for earlier diagnosis as the only means of escape. From the viewpoint of scientific advancement it is a cry of despairing ignorance, but from that of clinical surgery it is truth; for instrumental methods will never be able to do more than put right the mechanical upset before the serious onset of ileus. Also, however early the diagnosis may be made in cases of organic obstruction, there will yet remain the paralytic ileus of metabolic origin, still as deadly as ever and still as misunderstood.

Animal experiments have produced many theories in explanation of the toxæmia of this condition. Their number and variety are alone sufficient proof of their fallacy. In turn there have been suggested intestinal decomposition, bacteræmia, the proteose level of the duodenum; autolysis of mucosa, interference with circulation or with nervous reflexes. These and others have one point in common which stands out clearly on close investigation; each and all must be the result of some basic upset of physiology, itself the prime moving cause.

THE BASIC CAUSE OF ILEUS.

There are, however, two views on this subject which are much to the fore at the present time, the action of bacteria, especially of the anaerobic variety, and the toxic element found in obstruction fluid. A careful analysis of these will, I think, take us some way along the road in our search for a more basic cause of ileus.

In 1882 Koch discovered the tubercle bacillus, but the disease associated with it still works havoc among the nations. The only reasonable explanation of this must lie in the fact that the organism is not of itself the first cause of the disease. This must primarily be due to some upset of normal physiology, to some discord in the harmony of health which allows the organism free play. This is true of all pathogenic bacteria. What of the virulence of these workers of evil in our bodies? Through a series of laboratory subcultures this is lost, and it is restored by passage through a number of living animals. So even the virulence of the organisms is dependent upon some close association with the vital processes of a possible host.

In this light consider the bacterial content of the alimentary canal. In health the upper part is amicrobic, whilst the number and the virulence of the organisms increase along the length of the intestine from above downwards. In obstruction the function of the muscular wall of the intestine is upset from below upwards, and with this procession of loss of normal physiology goes the growth in the number and virulence of the bacteria. In a state of health there is then, according to this argument, some physiological process in the upper portion of the small intestine which is inimical to the life and growth of micro-organisms, and the intensity of this protective action diminishes along the length of the canal. In the general plan of concentration of a particular function in a particular organ, to supply the needs of the whole body, is it possible that this mechanism operates locally in the upper portion of the small intestine for the necessity of the whole organism? Such a theory offers a really basic explanation of the early gravity of high obstruction as compared with one low down, since the higher up the initial site of obstruction is placed, the greater will be the loss of this vital physiological function at the commencement of the trouble.

In the fluid found in obstructed intestine, whether of organic, paralytic, or experimental origin, there is present a toxic element which on intravenous, intraperitoneal, or subcutaneous injection causes death with symptoms like those of the original disease. There are, moreover, definite findings associated with the death following the injection of this fluid which are seen on post-mortem examination. The gastric mucosa shows marked hæmorrhagic changes; the pylorus stands out by reason of the pale pink colour of the mucous membrane which covers it, whilst just beyond the level of the sphincter there is a sharply drawn line where the dark red injection recommences in the duodenum. Here it is as marked as it is in the gastric mucosa, but the intensity of the damage fades in the lower part of the small intestine. The mucosa of the pylorus seems untouched; no ulcers commence at the pylorus; the whole picture is brimming over with suggestion. There is strong evidence that this poison is not formed in dead tissue but that its production is dependent on the vital activity of the cells. Van Beuren [1] relates the case of a girl who died of ileus 48 hours after an appendicectomy; the fluid from her intestine killed a dog in three and a half hours. For class purposes he made a volvulus in a dog, the animal dying in 18 hours. There had been complete stasis of contents and of circulation since a ligature was tied tightly round the base of the volvulus. The fluid from this gangrenous loop was non-toxic when injected into the veins of another animal. Braeze,[2] in working with a duodenal loop, which could be emptied at will through the abdominal wall, found it was not until after the lapse of about 36 hours that there was a demonstrable amount of toxic substance in the loop fluid. There also appears to be agreement among observers that the degree of

toxicity does not bear any constant relation to the amount of damage sustained by the tissues of the loop. Ellis [3] has succeeded, by extraction with boiling water and the precipitation with alcohol, in isolating a toxic material from obstructed intestine of both organic and paralytic origin. On injection this gave rise to death with symptoms of acute ileus. He has managed to carry the original dose of toxin injected through a series of four dogs—that is to say, a dose of toxin from a case of ileus was injected into the first dog and the extract of the duodenum of this dog after death was put into the second dog and so on. Of this series of four dogs so dealt with, the first three died in the usual way, whilst the fourth, although exhibiting marked symptoms, eventually recovered. Ellis's comments are as follows:—

"These experiments also show that the toxin circulating in the blood stream can apparently excite the cells of the intestinal mucosa to the formation of the poison, for if one considers the small amount of the toxin solution injected, and the large amount of dilution which must occur in the blood stream and in the tissues, and the loss incident to the necessarily crude method used in recovering the toxic element from the intestinal content, then one must conclude that it is not possible that we are dealing with the recovery of the original dose."

Objection has been raised to conclusions drawn from these results of intravenous injections on the ground that this does not occur in actual cases. It is stated with truth that this toxin is not absorbed from healthy intestine, and since its presence cannot be denied, a damage to the mucous membrane has been demanded as a necessity for its absorption. What damages the mucosa? So once again we are forced back to bed rock if we are really to solve the problem in a fashion which will help us in treatment. Now how are we to attempt an explanation of this series of experiments of Ellis?

It appears that a small amount of the toxin injected into an animal is capable of starting a vicious circle which results in death; in the duodenum of such an animal a similar poison is found in increased amounts. The primary dose has resulted in a generation of itself.

EXPERIMENTAL WORK.

Now to turn from the universe of speculation to the closer confines of experimental and clinical facts.

The starting-point of my endeavours in this direction was the work of Whipple and his co-helpers.[4 5 6] These observers isolated a washed loop of the duodenum, thereby excluding any possibility of decomposition of intestinal contents. A ligature was tied round the gut just below the entrance of the bile and pancreatic ducts, whilst a second was placed beyond the duodeno-jejunal flexure. The continuity of the alimentary canal was reconstructed by the performance of a posterior gastro-enterostomy beyond the lower obstructing ligature (Fig. 1). These animals all died within three days at the outside, whilst many of them did not survive longer than 48 hours. The dogs died with symptoms of an acute intoxication, subnormal temperature, fall in blood pressure, and venous congestion. The mucosa and the fluid content of the loop contained a toxic body which caused death in a few hours when injected into another dog. The time of survival depended on whether the fluid was put in by vein, peritoneum, or subcutaneous injection. If Whipple destroyed the mucosa by means of a chemical such as sodium fluoride, prior to isolating the loop, he could no longer find any toxic substance in the fluid. Having excluded all food remnants and the digestive juices of the liver and pancreas, he concluded that the poison was formed by the action of the bacteria on the cells of the mucous membrane, and that on absorption into the circulation it caused the death of the animal. Now it has been shown that an animal can live for weeks or even months with a similar loop formed in the lower ileum or colon.[7] It is hard to explain how the bacteria-laden loop of the lower bowel is thus innocuous whilst that of the previously sterile duodenum is so rapidly fatal, if the bacteria really do play a primary part in the formation of this poison. So once again we are thrown back on the mucosa of the duodenum and some upset of its normal functioning.

In the first place I repeated the exact procedure of Whipple (Fig. 1). To obtain a complete closure of the lumen of the intestine without cutting through into the interior of the gut I used, as did Whipple, a thick strand of string (Fig. 2). This was tied as tightly as possible, and then it was buried by bringing the peritoneum of the intestine above and below together with a continuous Lembert suture. I have performed this operation without any additions or subtractions on three dogs. The animals all died as Whipple describes within 36 hours. There is, however, one feature of their death which is worth noticing. In the case of two of these dogs I saw the animals within 10 and within 15 minutes of death respectively. They were obviously very ill, very toxic, and vomiting persistently. When I called to them, however, they had strength to get up on their feet and walk across the cage to me, and when I patted them they were sensible enough to wag their tails. Yet within those few minutes they were dead. Something had suddenly failed and the vital processes had stopped. It is not absolutely unlike what happens at times in the clinical experience of us all. The condition of a patient, after an apparently successful operation for acute obstruction, suddenly changes, and he dies rapidly without exhibiting any obvious cause which we feel we can put a finger on. The whole suddenness of the change and the rapidity of the passage of subsequent events forces the conclusion that some vital reaction was at this stage suddenly interfered with.

Since all observers have secured the same results in this operation the actual facts cannot be controverted. The conclusion which Whipple drew from them has in no wise helped us to abate the ravages of death in this condition. The only reason for this must be that though the facts were correct the conclusion drawn was wrong and the cause of death was not as he thought.

Let us carefully consider what exactly it was that Whipple did (Fig. 1). He put a large portion of the duodenum out of action, converting it into obstructed intestine. But he did much more; he obstructed the remaining part of the duodenum above his first ligature together with some portion of the stomach. Whipple claimed that the loop poison was the cause of death. It was at once apparent that it was possible to keep the loop intact and yet to eliminate the further upset of the alimentary canal which I have indicated. By performing a lateral anastomosis immediately above and below the two ligatures the loop is left exactly as before, whilst the continuity of the rest of the intestinal track is secured. (Fig. 3.) One dog, which had had this operation performed, was very much alive and able to take a keen interest in what went on around him ten days after this obstruction of the duodenal loop had been brought about. All the other dogs treated after the manner of Whipple have died in under three days, but on the fifth day after his operation this dog was busy worrying a dead mouse which he had killed in his cage during the night. Although this animal did not succumb to the loop formation as did the other animals, there were very marked signs that all was not quite well with him. There was great loss of flesh, although after the first 48 hours there was no difficulty in getting him to take a certain amount of milk and starchy foods. He exhibited a curious spasticity of the limbs, especially of the hind legs, and furthermore he could not keep still above a few seconds. This purposeless choreic-like movement is reminiscent of the restless tossing and pulling at the bedclothes which is often such a marked feature of the terminal stages of human cases of ileus. There were no symptoms of the acute intoxication which the other dogs had exhibited and this animal never vomited. On the tenth day just after this photograph had been taken, I killed

the animal and immediately did a post-mortem examination. The peritoneal cavity was dry and clean. The site of the operative procedures was still clothed with the omentum which had been laid round it at the time of operation. The lateral anastomosis was functioning perfectly and bile-stained intestinal contents could be seen above and below the opening. The ligatures still completely blocked the lumen of the gut at both ends of the obstructed loop. The interior of the isolated segment of the duodenum was empty of any food content and no trace of bile staining could be seen. This dog was not killed by the presence of the duodenal loop.

A possible argument against this result could be brought on the grounds that the ligatures might have loosened sufficiently to allow fluid to enter or leave the loop even though only in minute quantities. To make certain on this point, in the next dog I completely divided the intestine above and below the two ligatures and invaginated all four ends. By this means the loop was entirely cut off from the rest of the gut whilst the blood and nerve supply remained intact. The lateral anastomosis was completed as before (Fig. 4). An operation was performed on this animal on March 13th. It suffered no acute symptoms, neither did it vomit. It remained well until the afternoon of March 17th—that is, exactly four days after the formation of the loop. In the evening a sudden change came over the dog and it was dead before morning. A post-mortem examination revealed a perforation in the wall of the loop with general peritonitis. It had, however, survived for four days during which time it did not vomit and it exhibited no symptoms of an acute intoxication such as the dogs did after Whipple's operation. It is clear, I think, that this dog did not die as did the dogs in his series. This was killed by an accident which does not always happen. This question of perforation of the loop is interesting. It is something far more subtle than a mere rupture of the intestinal wall due to distension with fluid. To the naked eye it is the most perfect replica imaginable of a perforation of an acute duodenal ulcer, whether viewed from the inside or from without. Another feature which is also at present unexplained is the varying amount of fluid which accumulates in the isolated loop. In one dog the loop will be tense with a watery blood-stained content, whilst in another animal the loop is collapsed and has only a thick paste-like content. The contraction of the loop in this case is not associated with any leakage from a perforation or rupture. It is in absence of active secretion for some reason. These experiments do show, I think, that it was not the loop which killed Whipple's dogs, though there is evidence that it can seriously upset their normal health. It is quite clear at any rate that an isolated loop of duodenum is not incompatible with life over a much longer period of time than his dogs lasted.

There is another series of experiments done by Eisberg,[8] which illustrates the same point though the actual operation was different (Fig. 5). If a simple ligature is placed round the intestine just below the entrance of the bile-duct, the animal dies rapidly, in 36 hours or so, with symptoms of fulminating intoxication. If, however, the obstruction is placed above this entrance, just below the pylorus, the symptom complex is changed and the animal lives for a considerably longer period of time. This difference is markedly exemplified in our clinical experience with man. The case of simple pyloric obstruction lasts for a lengthy period, whilst the occurrence of a vicious circle after a gastro-enterostomy rapidly ends the scene with a picture which is indistinguishable from that of acute ileus. One essential difference in the physiological results of the positions of these obstructions is that in the one the bile has a free and uninterrupted passage along the length of the intestine, whilst in the other it is held up at its origin and is in part lost from the body by vomiting. The same difference exists between the method in which Whipple performed his loop operation and the way in which I did mine. I now assumed for the purpose of experiment that it was essential for life that bile should be in contact with the intestinal mucosa; and the idea occurred to me that it might be possible to get this condition restored in cases of acute ileus by placing bile in contact with the mucous membrane of the rectum.

The following question will at once present itself if I have made the argument clear: "How is putting the bile into the rectum going to allow bile to have access to the duodenal mucosa: insistence has been laid on the importance of the function of this portion of the alimentary canal all through, and surely then if bile must be anywhere it is in the duodenum where its presence is vital?" It may be well to state that much remains to be done before the scientific basis of the relief produced in paralytic ileus by the injection of bile can be established. In the present lecture I do not propose to deal with the experimental

work I have performed to obtain an insight into the mode of action of this therapeutic measure.

I shall briefly describe some of the clinical results of this method of treatment; pointing out the difficulties met with, as well as the successes attained.

METHODS AND TECHNIQUE.

The first time that an opportunity presented itself for trying out my hypothesis, as it then was, I was suddenly confronted with an acute ileus in the case of appendicectomy which had been left in my charge. It happened at a moment when there was no bile available save that which was contained in the patient's own vomit. Thinking that the acid content of the vomits might act as a severe irritant to the rectal mucous membrane I diluted the vomits with normal saline. As this stopped the vomiting effectually I continued the practice of dilution even when pure human bile was to be used. Another reason which influenced me in making this decision, was the thought that the increased bulk of the fluid would allow more of the bile to come in contact with the mucosa of the rectum. If possible, freshly secreted human bile from a cholecystostomy was used, but I have found that the bile can be kept in an ice-chest, for at any rate a week, without losing any of its potency.

The technique used in this series of cases has been to commence with 2 oz. of human bile in 4 oz. of saline. This mixture is run into the rectum with a tube and funnel in exactly the same way as an ordinary saline is given. The procedure is repeated every four hours. There is no discomfort caused by using human bile and the patient does not experience any difficulty in retaining the injection. If however, ox-bile is used, the desired effects are not obtained so easily, nor so quickly, and acute pain of a colicky nature appears; pain so severe as to call for the use of morphia. Also at the end of half an hour or thereabouts the patients often declare that they are forced to return it against all will-power and effort to the contrary. If human bile is now used for such a patient there is no further trouble, the saline is retained with ease and the desired results accrue more rapidly. The same pain was caused by the use of vomited bile in the only case in which this form was employed.

It will at once occur to many that the use of ox-bile as an enema is an ancient practice which has been in large measure discarded. I must say that although the bile is given per rectum it is not as an enema that it works. The results of this treatment which I am about to put before you will follow its use in a case of unrelieved organic obstruction without any passage of either fæces or flatus. If the full remission of the toxæmia and its accompanying symptoms is not obtained, the amount of the bile is increased by increments of half an ounce at a time, the dilution remains in the same proportion. I have not had to go beyond 3 oz. of bile at a single injection before obtaining the results aimed at.

The question of how long this treatment is to be persisted in, is not an easy one to answer in a few words. The work is only in its early stages and much has yet to be learned. It is, however, safe to state that when definite improvement is seen and the bowels have been opened it is safe to ease off the amount of bile. If the vomiting returns it is possible to get the patient under control at once again by increasing the amount of bile to that which previously was efficacious. The histories of the cases will show the difficulties met with in this form of treatment. One of the greatest of these arose from the fact that it is possible to keep a patient fit for days even though there is an unrelieved organic obstruction inside his abdomen. Obviously this result is simply one of cloaking a condition demanding surgical interference. In fact, my experience goes to show that if the vomiting returns on the cessation of the bile, and at the same time the bowels are not open in a satisfactory manner, then the abdomen must be reopened, as it is almost certain that there is a mechanical obstruction present.

In the first cases morphia was used in conjunction with the injection of bile. Those who are acquainted with the writings of Hugh Owen Thomas on the place of this drug in acute obstruction will very naturally suggest that the whole effect is due to the morphia. Repeated injections of morphia were used in only one of these cases in which human bile was the form used. It was afterwards found unnecessary except for special occasions. Opium can, and I think should, be used with discretion, but only after the patient has been got under control with the bile. There is a very distinct danger in using morphia, in a case with an advanced degree of toxæmia, before this has been accomplished. Another possible explanation which I can see may be put forward is that the result is due to the fluid absorbed from the rectal injection. Only 4 oz. of saline have been used in each injection, and if saline in itself is a specific for the toxæmia of acute ileus, this fact would have been recognised long ago. The diet of these people is most important. It is absolutely essential that nothing but water and orange juice should be given until the ileus is overcome and the bowels are working naturally. Glucose in this form is useful and I believe expedient. This is, I believe, the only addition to water allowable. In my experience anything in the nature of meat extract is promptly returned.

The present series is composed of 13 cases of acute ileus which had all reached the stage at which the vomited material had a distinct stercoral odour and appearance. It was quite obvious that really startling evidence had to be produced, and therefore mere distension and mild vomiting would be no kind of proof of the value of a specific treatment which is said to result in the disappearance of the vomiting and other phenomena of acute obstruction. Also I did not feel justified in testing this method of treatment except in extreme cases for which nothing else could be done.

CLINICAL HISTORIES.

Case Treated with Vomited Bile.

CASE 1.—The patient, a man of some 30 odd years, had a gangrenous appendix removed some days previously, with drainage to the pelvis. His condition gave rise to a good deal of anxiety owing to distension and flatulence. Without any further warning he started to vomit profuse amounts of foul-smelling bile-stained material, and with this there developed a marked hiccough. There was no other form of bile available, so the vomited matter was diluted with saline and put back into the man per rectum. The vomiting stopped forthwith, whilst the spasm of the diaphragm was lessened and had disappeared within 18 hours. The treatment was continued until all the vomitus was used. The injections caused him to suffer intense colicky pain, which had to be controlled with morphia. Within 24 hours the stercoral vomiting had restarted and was again abolished by the same methods. There was no further recurrence, and after a stormy convalescence he recovered without any more ileus.

Case Treated with Human Bile.

CASE 2.—This was a private case in which I had removed a gangrenous but non-perforated appendix within 30 hours of onset. There was a small amount of slightly turbid fluid in the pelvis, and the abdomen was closed without drainage. For the next three days he gave rise to no anxiety, and a fair result was obtained each day with a simple enema. There was a slight amount of flatulent spasm, which would be expected in such a case. On the evening of the third day he was a little distended and vomited once, but only some water which he had taken. An enema resulted in the passage of flatus followed by a small fæcal result. I was sent for in the early hours of the morning and found that he had quite suddenly vomited a large bowlful of stercoral material. He was propped up in the Fowler position hiccoughing persistently. His abdomen was tightly distended, the facial expression drawn and anxious; the pulse was thin and running. Operative measures were quite out of the question; indeed, he looked very near to death. I made the diagnosis of a fulmination of a quiet paralytic ileus. Subsequent events proved me wrong, but an immediate operation would have resulted in death. I put him on four-hourly salines of human bile with ¼ gr. of morphia hypodermically at the same intervals. In view of the acute pain caused by the injection of vomited bile in the previous case, I expected at this stage of my investigations that the same pain would

follow the use of human bile. By the evening he was comfortable though still very distended. He had not vomited since the first bile injection had been given, and the hiccough ceased to worry him within three hours. This course was continued for seven days, during which time he had taken nothing save water with a little orange juice. On the evening of the seventh day I stopped the bile, still continuing the morphia four-hourly. The next morning he again vomited up copious amounts of definitely fæculent material. The bile was restarted and the vomiting again stopped forthwith.

Two days later I stopped the morphia continuing the bile. He still remained comfortable, as the distension had in large measure disappeared and his pulse was 70. His tongue was moist and perfectly clean, though his bowels had not moved for ten days. On the tenth day I ordered two enemas, and as there was no result of any kind I realised that it was not a case of paralytic obstruction. I went in to break the news to him and found him with a soft and only slightly distended abdomen, a pulse of 70, a perfectly clean moist tongue. He was smoking a cigarette and reading a paper. I had great difficulty in persuading the patient to allow me to open his abdomen, as he insisted that he felt perfectly fit and well. Moreover, he looked it. I gave him 3 oz. of bile per rectum half an hour before operation. He gave no trouble to the anæsthetist and did not vomit after the operation. I reopened his abdomen through a small pararectal incision, and found that there was an absolute obstruction by an omental band about six inches from the ileo-cæcal valve. The bile was continued for two days; the bowels were well moved the morning after this operation, and he made an uninterrupted recovery.

This case taught me that morphia was not needed for pain when human bile was being used. It will naturally be asked, but why sit on a case all that time? When bile is being used in a case of organic obstruction such as this the residue of the bile collects in the large bowel and is voided at intervals, especially after an enema. This material looks and smells just like a fluid stool, and in this case it deceived me into thinking that we were gradually overcoming the paralysis since the distension was less. I even had an enema given, the amount injected being measured before and after its return. The volume was always increased after being returned, and it was some time before I hit upon the true explanation. Also I had not yet realised that the abdominal distension went as a result of this treatment without any passage of flatus. It can now be realised that the first steps in the clinical application of this work were beset with many difficulties which did not always allow of a successful ending, as will be seen later.

Since human bile is often difficult to obtain, I decided to try the effect of ox bile. The dose was half the quantity of that employed when human material was used.

Case Treated with Ox Bile.

CASE 3.—A girl, aged 25, had a gangrenous appendix removed on Dec. 19th; the abdomen was closed. Her abdomen was a little distended and she vomited slight amounts on several occasions, but there was no sign of any stercoral odour. On the 24th she was very distended, the outline of the stomach itself being plainly visible below the level of the umbilicus, and the material brought up was of distinctly fæcal odour. As no human bile was procurable she was given 1 oz. of fresh ox bile four-hourly in saline. The vomiting ceased gradually, the abdomen softened, and on the 28th the bile was stopped. Within 12 hours both the distension and the vomiting were worse than ever. The treatment, still with ox bile, was restarted and continued until Jan. 4th, when the distension had almost disappeared, and as the bowels were acting daily the bile was stopped. The subsequent history was one of uninterrupted progress.

It was obvious from this case that although the ox bile did work it was far less efficient than human bile, whilst it caused acute pain which had to be relieved with morphia. It seems that there is some harmful substance in this form of bile which causes these symptoms. The results were not all of this happy nature.

Case in which Ox Bile did not Work.

CASE 4.—A woman, aged 60, had a cæcostomy performed for acute obstruction due to a growth of the hepatic flexure. She had fæculent vomit on admission and this continued after operation. This ceased with human bile, but after a day this ran short and recourse had to be taken to ox bile. The vomiting returned and was again allayed by human material. I saw her on the fourth morning looking very fit and the vomiting had almost ceased. She was suddenly seized with acute abdominal pain and vomited persistently in spite of all until her death three hours later. Post-mortem examination showed that the cæcum had slipped back and filled the peritoneal cavity with fæces.

Case in which the Bile Failed after Primary Success.

CASE 5.—A man, aged 35, had an acute gangrenous appendix with an ileus duplex at the time of operation. Drainage to the pelvis was employed, and at the same time an ileo-transverse colostomy was performed. This was on Jan. 4th. On the evening of the 6th he suddenly collapsed and began to regurgitate rather than vomit fæculent matter. He had a muttering delirium and was plucking at the bed clothes. Human bile was given and the vomiting had almost ceased next morning, whilst the man's condition was greatly improved and he said he felt better. The improvement continued day by day, but on the 11th the vomiting recommenced and persisted in spite of all efforts. I did not see him myself after the 10th, and those who did see him thought that his death was due to a progressive general peritonitis. In the light of experience gained from subsequent cases I cannot rid myself of the suspicion that a recurrence of some obstruction was really the cause of his death.

In all, 13 cases have been treated with this method. They were cases of an extreme degree of ileus, all with stercoral vomiting. Of this number four have died—one as a result of leakage from a cæcostomy into the peritoneum, another from a cause which was never settled as a post-mortem was refused. The remaining two fatalities were due to an unfortunate happening which was the result of ignorance of the potency of the treatment and which I think can be avoided in future work. I will now describe these two cases.

A woman of 65 was admitted to hospital with a strangulated femoral hernia on Feb. 2nd. The hernia was operated on, and the gut, which quickly regained its colour, was returned. The radical cure was completed in the usual manner. Two days later she commenced to vomit stercoral matter and this was controlled with human bile. Three days later the vomiting restarted and continued at intervals. All the time the patient looked remarkably fit. On two occasions I thought of reopening her abdomen, but she was so frail that it was not done. She died on Feb. 18th. The post-mortem revealed a strangulated loop of intestine in the other half of a bilocular hernial sac which had been reduced en masse at the time of operation. It is easy to be wise after an event, but the fact remains that with the administration of human bile this woman of 65 had lived for 16 days with complete obstruction due to a strangulated loop of small intestine within her abdomen.

The second case is of a similar nature.

A woman, aged 30, was admitted with abdominal pain and vomiting. The diagnosis was acute obstruction. At operation a band was found and divided. Three days later the vomit was fæcal and the treatment by human bile was started. On the fifth day, since she had not vomited again, the bile was stopped. Her bowels were well opened as a result of an enema. Two days later the vomiting began again, and this time it was only stopped when morphia was given in addition to the bile. This alternation went on until 15 days after her operation, when there was a copious fluid stool. I now ventured to give her a small dose of mag. sulph. The fæcal vomit restarted and I said that there was some organic cause which had been missed at the first operation. She was given a bile enema, and on opening her abdomen an intussusception due to a polyp was found in the lower part of the ileum. It is evident from her history over these two weeks that this had only been present intermittently. The polyp was removed and a lateral anastomosis performed above and below, as the suturing after removal of the polyp had constricted the lumen of the bowel to a dangerous degree. She rallied from this procedure, but there was only ox bile available, and though I have no actual proof I feel that the substance in ox bile which causes the pain can not only not improve the condition, but can even be deleterious if given to a patient who is really badly shocked. (This danger is never to be feared when human bile is employed.) This case died on the second day after the operation.

These two histories are sad reading, but in a new form of treatment success cannot always be obtained. There are bound to be pitfalls and experience has to be bought at a price. The only consolation lies in the fact that they were cases in extremis when this form of treatment was tried, and that nothing else

could have done them any good with a greater hope of success. Their lives were undoubtedly prolonged, and with my present knowledge I do not think that failure would have resulted, since in both cases the operation would have been done many days earlier.

SUMMARY OF THE EFFECTS OF HUMAN BILE IN ACUTE ILEUS.

In most cases after the first rectal injection of human bile the vomiting stops forthwith, and even if this is not the result at once it is very much diminished, and an increase in the bile given will secure the desired result. The violent hiccough which so often accompanies ileus, especially in cases of primary small intestine obstruction, will lessen and disappear in a few hours. The drawn, anxious expression fades rapidly, and at any rate it is true to say that if you do not see the patient for some hours the change is so pronounced that it cannot be missed. The dry furred tongue will become moist and clean, and will remain so in spite of an unrelieved organic obstruction. In addition, the restlessness is abolished. The patient will volunteer the information that he feels quite a different person from what he did a few hours before, and his whole manner and bearing confirm this statement as being true. Perhaps the most striking manifestation is the softening of the abdomen and the disappearance of the distension, without any passage of flatus per rectum. One is forced to the conclusion that is has gone whence it came and has been reabsorbed.

It was thought probable on the basis of experiments on animals that the symptoms which develop in intestinal obstruction were due to some interference with physiological function, such as the absence of bile in the small intestine. For this reason bile was injected in human cases of acute ileus.

The experimental work for this lecture was done in the Pharmacological Laboratory of Sheffield University. I wish to tender my sincere thanks to Prof. Edward Mellanby for his kind help and criticism. The expenses were defrayed by a grant from the Royal Society.

STUDIES IN THE ACID-BASE EQUILIBRIUM IN PSYCHOSES.*

BY ISABELLA ROBERTSON, M.D. LOND.

THE GASTRIC FUNCTIONS.

THIS paper records the results of a series of observations on the gastric functions in certain types of mental disorder, and forms part of a research in the acid-base equilibrium in psychoses. These observations were carried out: (1) by an analysis of the gastric contents; (2) by an investigation of the variations in the alveolar CO_2 pressure following a standard meal.

Four groups of subjects were investigated. Only those who after a complete physical examination showed no gross physical abnormality were selected. The first group consisted of ten normal healthy men and women, the second of ten melancholics, the third of ten schizophrenics, and the fourth of ten cases of anxiety neurosis. The cases of mental disorder were all uncertified and of comparatively short duration. Each case selected, however, presented a typical clinical picture, and was subjected to fairly prolonged observation before any investigation was undertaken. Considerable difficulty was experienced in persuading the psychotic patients to swallow the fractional tube and in teaching them to expire normally through the mouthpiece of the Haldane gas analysis apparatus. For these reasons it was decided to confine the investigation to a comparatively small number of cases, and to investigate these cases thoroughly, rather than to examine a large number of cases once or even twice. The investigations were carried out under similar experimental conditions, and each patient was examined on several different days.

The first part of the investigation consisted of a series of observations on the gastric test-meal. Using the fractional tube for extraction and the gruel test-meal, a complete analysis of the gastric test-meal was made every 20 minutes. The free HCl and the total acidity were estimated, using dimethyl and phenolphthalein as indicators, and the results recorded graphically, the acid value being represented by the number of c.cm. of N/10 alkali which would be required to neutralise 100 c.cm. contents. The total chlorides were estimated by the Volhard method. One or two of the patients who eventually did swallow the fractional tube were so agitated on each occasion that the results obtained were valueless. In the majority of the patients who were finally selected a fairly considerable emotional disturbance occurred during the first one or two examinations, and the results were found to vary somewhat in consequence. This emotional disturbance was not noted during the later examinations, and the results obtained were of a characteristic type. That an emotional stimulus—e.g., fear—inhibits gastric secretion has been shown by T. I. Bennett and J. F. Venables (1920). J. R. Bell and W. McAdam (1924) have also noted that the lowest acid curve obtained after a test-meal is that obtained on the first examination, and that subsequently the free HCl is of characteristic type.

The second part of this investigation consisted of a series of observations on the variations in the alveolar CO_2 pressure following a standard meal. Changes in the alveolar CO_2 pressure following a standard meal in normal subjects have been demonstrated by E. C. Dodds (1921). He finds that during the first 30–45 minutes the alveolar CO_2 pressure rises 2–6 mm. Hg, subsequently falling to nearly the same extent below the original level—the lowest point being reached after one and a half to two hours—and regaining the original level three hours after a meal. In a later paper Bennett and Dodds (1921) have noted the correlation which exists between the curves of gastric acidity and the alveolar CO_2 pressure following a meal in normal subjects of varying types as regards their gastric secretion.

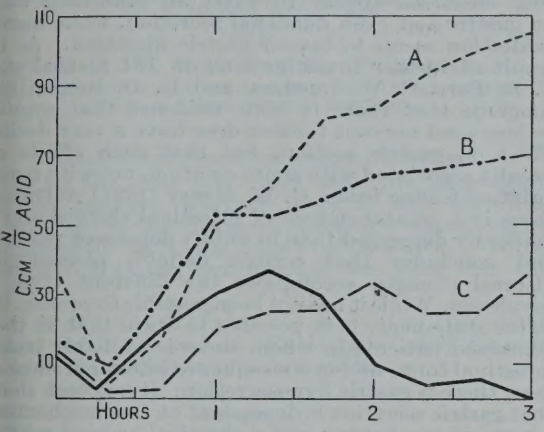
The analysis of the CO_2 percentage in the alveolar air was carried out by the Haldane Priestly method, using the Haldane gas analysis apparatus. A special burette, the bulb of which was capable of holding 18 c.cm. and the graduated stem 2 c.cm., was used.

Gastric Test-meal.—The variations in the results obtained from the same individual on different dates were slight, and even when the variation was maximum the general conformation of the curve was maintained. Generally, the curve obtained on the first day was lower than on any subsequent day. The average free acidity of the fasting juice was 12 c.cm. N/10 acid and the amount varied from 5–50 c.cm. The percentage of free acidity after ingestion of the gruel meal showed an initial fall at 20 minutes—then a steady increase, reaching a maximum—a free acidity of 30–50 c.cm. N/10 acid—about one and a half hours followed by a gradual fall. C. Bolton and G. W. Goodhart state (1922) that the curve of acidity due

* This communication forms part of a report to the Medical Research Council.

to free HCl assumes in 90 per cent. the form of a single peak, and that the fall in the curve may result from neutralisation or dilution, or both. The curves of free and total acidity showed a difference of 15 c.cm. N/10 acid, and ran closely parallel. Generally, the stomach emptied in two hours. These results are in agreement with those of Bennett (1926), J. Ryle (1926), and H. McLean (1925). (Fig. 1.)

FIG. 1.



Curves of gastric acidity. The continuous line represents free acidity in normal subject. A = Agitated melancholic. B = Schizophrenic. C = Early schizophrenic showing atypical curve.

Alveolar CO_2 Pressure.—The variations in the alveolar CO_2 pressure following both a standard meal and a gruel test-meal were next investigated. The alveolar CO_2 pressure was expressed as mm. Hg, and the results recorded graphically. It was noted that the same type of curve was obtained on different days from the same subject, though the actual figures might vary from day to day. The results were in agreement with those of Dodds—a rise in the alveolar pressure following a meal, generally maximum at 45 minutes, and a subsequent fall, maximum at one and a half to two hours—and regaining the initial level at two and a half to three hours.

A comparison of these curves with the gastric curves of the same subjects shows that a definite correlation exists between the gastric acidity and the variation in the alveolar CO_2 pressure, the increase in CO_2 pressure varying directly with the amount of gastric HCl secreted. It has been shown by Dodds and Bennett (1921) in a series of observations that the subsequent fall in alveolar CO_2 pressure which occurs is due to secretion of alkali into the duodenum, and that this secretion is chiefly pancreatic in origin (W. Boldyreff, 1914–15). (Fig. 2.)

Results in Melancholia, Schizophrenic, and Anxiety Groups.

Melancholia Group.—These cases were all men of early middle age, free from gross organic disease. All were typical cases of melancholia occurring in men of a good type who had made a good adaptation until the time of breakdown and had been free from nervous or mental disorder. In slightly over 50 per cent. of the cases a history of abdominal pain, varying from definite epigastric pain to vague abdominal discomfort, was elicited.

The number of cases examined was too small to allow of any generalisation, but it did appear that there was a definite abnormality in the gastric secretion of melancholics. Only one case showed a definitely normal type of secretion. The results obtained from these ten cases were: normal, one; hyposecretory, six; hypersecretory, two; and atypical, one.

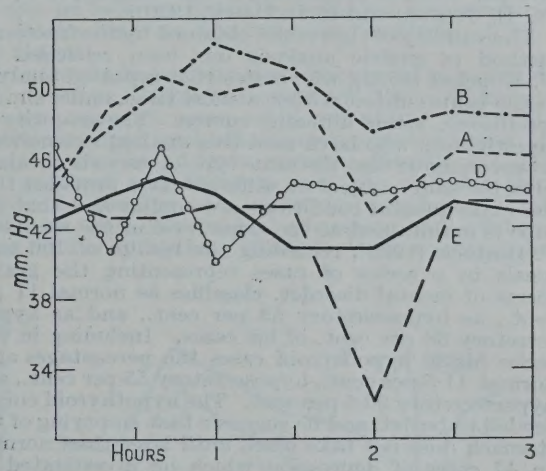
Schizophrenic Group.—In the adolescent psychoses diagnosis is admittedly difficult in the early stages, and since these cases were seen at a very early stage of development each member of the group was submitted to fairly prolonged observation before investigations were made. Subsequent histories have proved the diagnosis to be justified. All were of the hebephrenic type and in none had dementia supervened at the time of investigation.

In this group also the majority of the patients showed both abnormal gastric curves and correspondingly abnormal alveolar CO_2 pressure curves. The results of these ten cases were: normal, two; atypical, two; and hypersecretory, six.

Anxiety Group.—This group consisted of typical cases of anxiety neurosis. These were all young men, free from organic disease. In none of the cases could the onset be said to date from factors in the present life of a previously sound normal individual. Four of these cases, who were either quite unable to swallow the tube or, having swallowed it, to retain it for more than five or ten minutes, gave a constant type of alveolar CO_2 pressure curve. Three showed a marked and unduly sustained rise throughout, indicating hypersecretion or deficient pancreatic secretion, while the fourth showed no rise other than a slight and transient rise above the initial level at one and a quarter hours.

In this group also the majority of the patients examined show an abnormal type of gastric secretion, this abnormality being, as in the schizophrenic group,

FIG. 2.



Alveolar CO_2 pressure curves. The continuous line represents normal curve. A = Agitated melancholic. B = Schizophrenic. D, E = Melancholics of depressed anergic type.

a hypersecretion. The results of these ten cases were: normal, three; hyposecretory, one; hypersecretory, five; and atypical, one.

Gruel and Casein Test-meals.

Before discussing these findings it was considered advisable to compare the gastric secretion following the ordinary gruel test-meal with the gastric secretion following a pure protein meal of casein. A comparison of the gastric secretion following the gruel meal and the casein meal shows that casein produces a more intense gastric secretion than does gruel, this difference being due to the dynamic effect of the protein molecule. The general conformation of the two curves, however, indicates that the type of gastric secretion is unaltered, the difference being rather one of degree.

Discussion of Results.

The results obtained from the three groups of psychotic patients, based on an analysis of over

150 fractional test-meals and over 200 alveolar CO_2 pressure curves, were as follows :—

—	Normal.	Hypo-secretory.	Hyper-secretory.	Atypical.
Melancholia ..	1	6	2	1
Schizophrenic ..	2	—	6	2
Anxiety neurotic.	3	1	5	1

A comparison made between the gastric secretory curves following a pure protein meal and that following the conventional gruel test-meal showed that in both types of meal this abnormality persisted and hence could not be ascribed to abnormal response to types of food. The alveolar air curves corresponded in a normal fashion with the gastric acidity curves. A comparison of the gastric and alveolar CO_2 pressure curves of the same patient showed that a definite correlation, such as exists in normal subjects, does exist between the two types of curves. In classifying a patient, therefore, as hyposecretory or hypersecretory it was possible to confirm the gastric analysis by means of the alveolar CO_2 pressure in the majority of the patients, the exceptions being those patients from whom it was impossible, owing to lack of coöperation, to obtain reliable specimens both of gastric contents and of alveolar CO_2.

In the group of normal men and women who acted as controls none showed either hypochlorhydria or hyperchlorhydria. It has been shown that hypochlorhydria exists in 4 per cent. of apparently normal people and similarly that hypersecretion is found in 4 per cent. of apparently normal healthy subjects (M. E. Rehfuss and P. B. Hawk, 1920).

The validity of the results obtained by the fractional method of gastric analysis has been criticised by N. Kopeloff (1922), who states that repeated analysis in the same subject within a short time, under similar conditions, yields different curves. The majority of investigators who have used this method extensively, however, agree that the same type of curve is obtained from the same subject on different days provided that the experimental conditions are similar and that the tube is maintained at the same level in the stomach. J. Bostock (1926), recording the results of 100 test-meals in a series of cases representing the graver forms of mental disorder, classifies as normal 11 per cent., as hyposecretory 53 per cent., and as hypersecretory 36 per cent. of his cases. Including in this series his 36 hypothyroid cases the percentages are : normal 11·5 per cent., hyposecretory 55 per cent., and hypersecretory 33·5 per cent. The hypothyroid curves tended to be flat, and he suggests that emptying of the stomach does not take place until later than normal. In 47 cases of depression which he investigated 26 shows either achlorhydria or hypochlorhydria and 15 showed hyperchlorhydria. There is, therefore, almost complete agreement between the results Bostock obtained from his cases of depression and the melancholia patients of the present series. Of his nine cases of dementia præcox, however, six were of hyposecretory type and only one of a hypersecretory type, while of the ten schizophrenia cases investigated in this series six were of a hypersecretory type.

Consideration of the melancholia group shows that those patients who were hyposecretory were depressed, anergic, and obviously suffering from some degree of intestinal stasis and that those patients who were agitated showed definite hypersecretion. One of the patients in this group who alternated between anergic and agitated phases of depression within a few days showed in both phases alike the same type of steadily rising gastric curve, with a free acidity of 85–100 c.cm. N/10 acid at the end of three hours. The effect of hyperacidity is to cause a retardation of the emptying of the stomach, and in this case it was noted that it was always possible to withdraw about 30–50 c.cm. of contents at the end of three hours. It was possible to examine this patient on many occasions, and the results of these examinations showed clearly in this patient that it is not the acute emotion of the moment which determines the type of gastric secretion, in whic case one would find it possible to correlate the anergi phase with hyposecretion and the agitated phase wit hypersecretion, but that the type of gastric secretio is determined by the general visceral tone, which i this particular patient was one of increased nervou tension. The gastric curve was, therefore, a hype secretory curve, even on the days when the patien was anergic.

C. B. Farr and C. W. Lueders (1923), on the basi of fractional studies in 46 cases, conclude that depres sing emotions appear to exert an inhibiting effec on gastric and even duodenal secretion, while menta exaltation seems to favour gastric digestion. As th result of further investigations on 191 mental case C. B. Farr, C. W. Lueders, and E. D. Bond (1925 conclude that there is some evidence that emotio or increased nervous tension does have a very decide effect on gastric section, but that such effects ar usually associated with acute emotion, not with a mer habitual feeling tone. G. W. Henry (1924) states tha there is a greater degree of intestinal sluggishness i markedly depressed than in mildly depressed patient and concludes that certain definite physiologic visceral changes accompany the different types psychoses. While it has not been possible to confirm th latter statement, it is possible to state that in thos depressed patients in whom there is probably lack intestinal tonus and in consequence intestinal sluggis ness, there is gastric hyposecretion. It has been show that gastric secretion is dependent on two mechanism a nervous mechanism and a chemical or local nervou mechanism, the latter acting through the productio of a hormone. In these depressed anergic patien it seems probable that both mechanisms are at fau and that the vegetative nervous system may b at fault in two ways, both through failure to initia gastric secretion and through insufficient intestin tonus, inefficient gastric and intestinal movement and in consequence an accumulation of the produc of such digestion as does occur.

In considering those other psychotic patients, t agitated melancholics and the schizophrenic-anxie groups, in whom there is generally gastric hype secretion, it seems probable that in the earlier stag of the disorder there is an overactive condition the vegetative nervous system acting on the produ tion of gastric secretion and the augmentation intestinal tonus.

Summary.

In this paper the gastric secretion and the correlat alveolar CO_2 tension has been studied with t following results: 1. A normal type of gast secretion was found in only 20 per cent. of the psycho patients. 2. Comparison of the gastric and alveol CO_2 tension curves shows that a definite correlati does exist between the two types of curve. 3. comparison between the gastric secretory curves follo ing a pure protein and a gruel meal shows that t abnormality persisted and could not, therefore, ascribed to an abnormal response to types of fo 4. There is evidence to show that depressed, aner patients belonged to the hyposecretory group and th those patients who were agitated showed defin hypersecretion.

In conclusion, I should like to express my indebte ness to Dr. F. L. Golla for his interest and guidance this research, to Dr. E. Mapother and his medi officers for facilities to carry out the research. Dr. E. G. B. Calvert and Capt. S. A. Mann, B.Sc., advice and helpful criticism, and to those members the staff of the Maudsley Hospital who acted controls.

ROYAL SOUTH HANTS HOSPITAL.—An extension the nurses' home and a new operating theatre at the Ro South Hants and Southampton Hospital have been ope by Lady Montague of Beaulieu. In the course of a year so it is hoped to have 200 beds in the hospital, but needs of the district will not be met until 300 beds available.

THE ASSOCIATION OF OW BLOOD CHOLESTEROL WITH THE OCCURRENCE OF FITS IN EPILEPTICS.

BY S. H. G. ROBINSON, M.B. LOND.,
FREEDOM RESEARCH STUDENT, LONDON HOSPITAL;

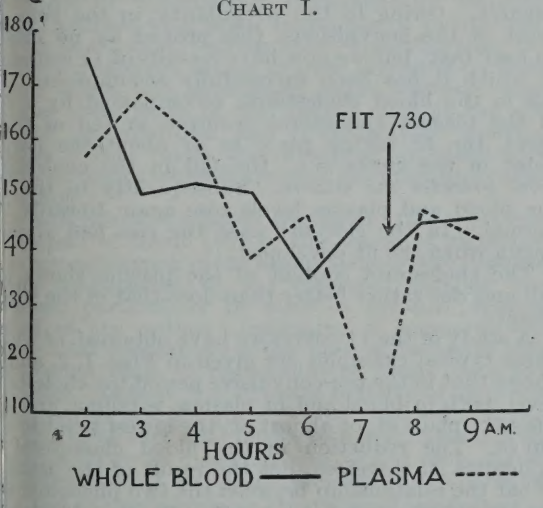
BEIT MEMORIAL RESEARCH FELLOW; BIOCHEMIST TO THE MEDICAL UNIT, LONDON HOSPITAL.

Biochemical Investigations of Epilepsy.

DURING the past few years attempts have been ade to discover whether there is any chemical normality in the blood of epileptics which might correlated with the onset of seizures. Thus, gwood (1924) has put forward the view that an

arts I., II., and III. show the Amount of Cholesterol (mg. per 100 c.cm.) in Whole Blood and Plasma Before and After an Epileptic Fit.

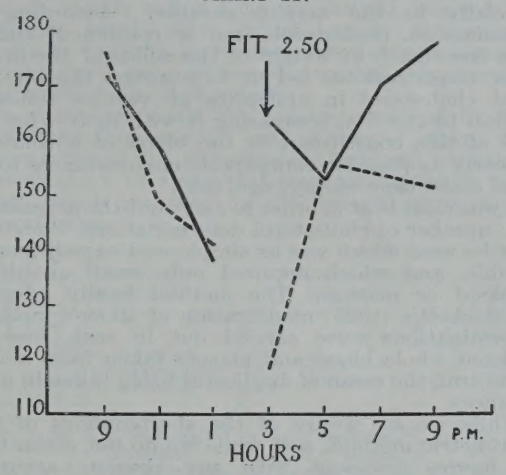
CHART I.



ileptic seizure is preceded by an alkalosis, which, leading to a diminution in the calcium of the blood, uses the convulsion. Marrack and Thacker (*a*) (1926) ve investigated the hydrogen-ion concentration of e blood of 34 epileptics and have found it to be thin normal range, even in patients having frequent s. They conclude that "a high plasma pH cannot considered to play an essential part in producing s." Further, Marrack and Thacker (*b*) (1926) have duced evidence to show that even if chronic slight alosis did occur in epileptics, it could not lead a reduction in calcium-ion concentration in the sma. They are of opinion, therefore, that pilepsy is not caused by a reduction in the calcium- concentration in body fluids."

Bisgaard, Norvig, and Larsen (1920, 1924, 1925) lieve that there is a great increase in the blood monia of epileptics before the onset of a seizure. is they attribute to a disturbance of the ammonia retion in these patients. Bisgaard has gone further d suggested that the "ammonia dysregulation is due parathyroid insufficiency." Luck, Thacker, and rrack (1925) find that a high blood ammonia may ur at times in epileptics, but not necessarily before s. Blood ammonia is high in starvation, for example, ondition in which epileptic patients are more than ually free from fits. High blood ammonia they do not consider to be the cause of fits. They also find no evidence of abnormal ammonia excretion in epileptics (1926). Wuth (1923) criticises theories regarding the ætiology of epilepsy based on changes which occur in the blood constituents during or after a fit. He states that non-protein nitrogen, uric acid, creatinine, and serum protein may show

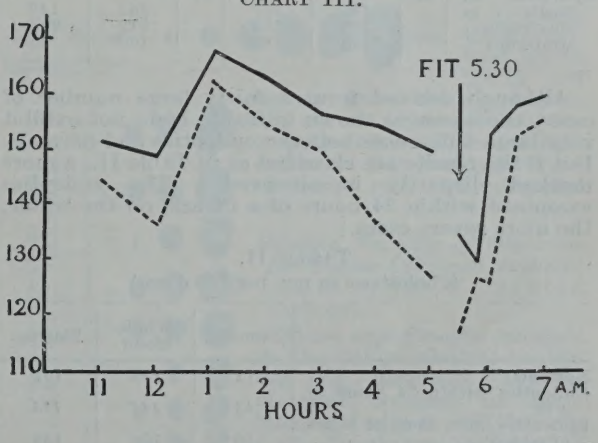
CHART II.



slight increases during and shortly after convulsions, but the changes are not always uniform, and are certainly not specific for a convulsive seizure. These changes he believes are to be regarded as secondary phenomena due to the physical exertion of the convulsions.

Negative findings of other observers may be included here. Lennox (1923) has examined the non-protein nitrogen, urea nitrogen, amino nitrogen, uric acid, creatinine, sugar, and alkali reserve in the blood of epileptics, and found them normal. Hamilton (1925) has examined and found normal the concentration of chloride, bicarbonate, inorganic phosphorus, total fixed base, and calcium in both serum and cerebro-spinal fluid of epileptics. Hitherto, then, no metabolic

CHART III.



abnormality in epileptics has been conclusively proved or generally accepted.

Blood Cholesterol in Epilepsy.

Apart from the use of sedatives, it has been found by different workers that epileptic seizures may in a number of cases be diminished in frequency (*a*) by starvation; (*b*) by a high fat diet; (*c*) during pregnancy. It has also been observed, and, indeed, been accepted as of value in diagnosis that, in epileptic women, fits are often increased in number and, in fact, may occur exclusively at or about the menstrual period.

In searching for some common factor we recalled that in the circumstances (*a*), (*b*), and (*c*) above when the fits are diminished in frequency, the blood cholesterol has been stated to be above normal (see Campbell's review, 1925) whilst at or about the menstrual period when fits are more frequent, the blood cholesterol is markedly decreased (Okey, 1925). Moreover, cholesterol and its esters form a quantitatively large part of the dry matter of nerve tissue and are present especially in the myelin sheaths. According to Hammarsten, cholesterol (free or combined) constitutes one-eighth by weight of the solids of the brain. These considerations led us to examine the level of blood cholesterol in epileptics at various times in relation to the fits, comparing it with figures for the level of this constituent in the blood of normals in as nearly as possible comparable circumstances (diet, social class, time of day, age, sex).

It was clear that in order to carry out the necessarily large number of cholesterol determinations, a method must be used which was as simple and expeditious as possible, and which required only small quantities of blood or plasma. The method finally adopted was Sackett's (1925) modification of Bloor's method. Determinations were carried out in each case on oxalated whole blood and plasma taken from a vein in the arm, the mean of duplicates being taken in most instances.

While we are aware of the shortcomings of this colorimetric method, and while we do not claim that our figures represent with any absolute accuracy the amount of cholesterol ("free" cholesterol + "ester" cholesterol) in the blood or plasma, we do claim that the results obtained for epileptic and for normal blood under similar conditions, are comparable.

The earlier results are summarised in Table I.

TABLE I.
(Cholesterol in mg. per 100 c.cm.)

—	Males.			Females.		
	No.	Whole blood.	Plasma.	No.	Whole blood.	Plasma.
Normals ..	39			32		
Mean ..		*172*	*163*		*175*	*172*
Maximum ..		222	212		243	217
Minimum ..		157	142		152	133
Epileptics ..	65			59		
Mean ..		*157*	*147*		*161*	*149*
Maximum ..		198	185		219	203
Minimum ..		100	85		100	95

Although derived from a fairly large number of cases, the averages shown in Table I. do not exhibit very large differences between epileptics and normals. But if the results are classified as in Table II., a more marked disparity is observed. (The epileptics examined within 24 hours of a fit are, on the whole, the more severe cases.)

TABLE II.
(Cholesterol in mg. per 100 c.cm.)

—	Number.	Whole blood.	Plasma.
Normals	71	173	167
Epileptics within 24 hours of a fit	45	*147*	*135*
Epileptics more than 24 hours after a fit	79	166	155

Popéa and Vicol (1925) have reported a few results which are in agreement with our own up to this point—i.e., they find that the blood cholesterol of epileptics is lower than that of normals, but they believe that the fall in blood cholesterol is the *result* of the attacks, and does not precede them. It became necessary, therefore, to determine whether the diminution which we had found was merely the effect of the muscular exertion of the fit.

In the first place we examined the level of blood cholesterol in eight normals (medical students) before, immediately after, and half an hour after a short period (one minute) of severe exercise which was deemed equivalent to that undergone during an epileptic seizure. The results are shown in Table III.

TABLE III.
Average blood cholesterol values before, during, and after exercise in mg. per 100 c.cm.

—	Whole blood.	Plasma.
Before exercise	190	172
Immediately after exercise	168	149
Half an hour after exercise ..	186	166

There was invariably a definite fall in the blood cholesterol immediately after a short bout of severe exercise. Cholesterol is taken out of the blood but how, or for what purpose, we are entirely ignorant.

It appeared, therefore, that the low blood cholesterol in epileptics might possibly be explained as the result of the muscular exercise of the convulsions. It must not be forgotten, however, that whilst in the normals of Table III. the cholesterol value rapidly returned practically to its original level after the sudden fall in the epileptics the cholesterol appeared to remain low for a much longer period.

We next examined the blood of epileptics at times immediately before and immediately after seizures. Owing to the irregularity in the time of onset of the convulsions, this proved by no means an easy task, but we now have records of 11 instances in which it has been successfully accomplished. A fall in the blood cholesterol, accompanied by a fall in the plasma cholesterol occurred in ten of the cases, the fit taking place at or about the lowest point in the curve—i.e., the fall in the cholesterol level *precedes the seizure*. Subsequently to the fit the blood and plasma levels rose again towards the normal. In the eleventh case the rise had already begun when the fit developed.

The cholesterol content of the plasma shows the fall and rise rather better than does that of the whole blood.

A study of the 11 curves we have obtained, of which three typical examples are given in Figs. 1, 2, and 3, shows that in the pre-convulsive period the cholesterol level, both in blood and in plasma, is falling, and the fits take place at, or almost at, the lowest point in the curve. The reduction in the blood cholesterol of epileptics is, therefore, not the result of the attacks. What the relationship between the two phenomena is we are not at present in a position to say. In view of the known connexion between the liver and cholesterol metabolism, the findings of Thom (1916) that the ratio of brain weight to liver weight is greater in epileptics than in normals may have significance in relation to our results.

The normal physiological rôle of cholesterol is largely unknown. Even less is known concerning the part played by this substance in conditions of disease. It is obvious that very serious difficulties remain to be overcome before the bearing of our findings upon the ætiology of epilepsy is made manifest. Nevertheless, we believe that the results we have presented above, pointing as they do to a definite metabolic abnormality in this disease, justify a more extended inquiry. With this we are at present engaged.

This investigation forms part of a research into the ætiology of convulsive states which is being conducted at the London Hospital and the Hospital for Epilepsy and Paralysis, Maida Vale, under the general direction of Dr. George Riddoch. It is a pleasure to acknowledge the help which we have received from Dr. R. Langdon-Down and Dr. J. Tylor Fox. Grants towards the expenses have been made by the Medical Research Council and the trustees of the London Hospital Medical College Research Fund.

EXPERIMENTAL CANCER:

TUDIES ON THE ACTION OF GLYCERINE ON TISSUE CELLS.

WITH AN ACCOUNT OF A METHOD OF RENDERING ULCERATED TUMOUR TISSUE RELATIVELY SAFE FOR TRANSPLANTATION.

Y ARTHUR COMPTON, M.D., D.Sc. N.U.I.,
DIRECTOR OF LABORATORIES, ALEXANDRIA MUNICIPALITY; LATE FIRST ASSISTANT (RESEARCH) SURGICAL CLINICAL UNIT, ST. MARY'S HOSPITAL.

A PROBLEM of considerable importance in experi-ntal cancer is that of the propagation of the erated tumour. Ulceration means infection, and ected tumour material, when transplanted into althy animals, results practically invariably in her abscess formation at the site of inoculation h subsequent ulceration, evacuation of pus, and th of the implant, or else—and this is the more quent happening—death of the animals in the ceeding few days from septicæmia. Thus, indeed, ny a tumour strain has been lost whose propagation ght well have proved of value in the ultimate ution of the cancer problem.

During the course of experiments on the treatment experimental tumours in mice according to cyto-rapy ideas, the writer found, while testing out effect of inoculating systematically tumour-ring animals with small fragments of devitalised, d as he thought, tumour cells—resulting from the tively prolonged action of pure glycerine on fresh nour tissue, and subsequent saline washing—that times there arose in the treated mice at the site such inoculations new progressively growing nours. This result was observed independently two occasions when it arrested attention and called inquiry.

As evidence of a marked degree of vital resistance the part of tissue cells to the action of glycerine, practical bearing of the observation on the problem the propagation of the ulcerated tumour was parent, particularly in view of certain previous dies of the author [1] indicating a comparatively ler vital resistance on the part of bacterial cells glycerine than of representative tissue cells like cocytes. Indeed, the ultimate toxicity of glycerine leucocytes and for staphylococci had been shown . cit.) to be such that leucocytes could presumably port a glycerine concentration 15 per cent. higher n staphylococci, an appreciable degree of difference.

To test the soundness or otherwise of the foregoing ception concerning the relative toxicity of glycerine tumour cells and for bacteria, as well as to fix approximate toxicity of glycerine for tumour cells mselves, were the objects of the present investiga-n, which is based on a series of experiments carried with a progressively growing highly virulent, transplantable mammary adenocarcinoma of the mouse, normally giving about 80 to 100 per cent. "takes" on transplantation into normal animals.

[1] THE LANCET, 1926, ii., 326.

Toxicity of Glycerine for Tumour Cells.

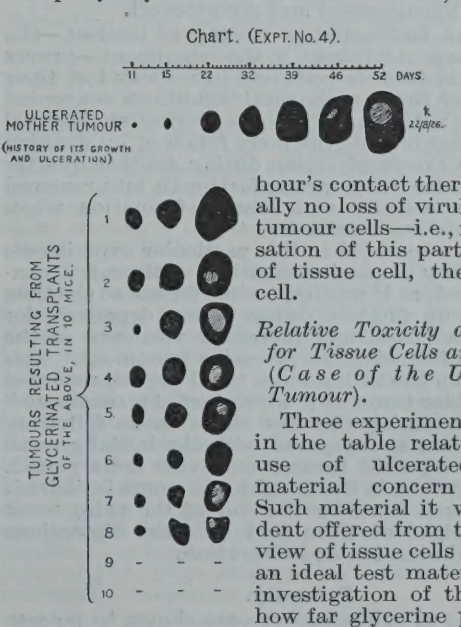
This was estimated by submitting small pieces (0·5 to 1 g.) of fresh tumour tissue to varying intervals of contact with pure glycerine, then washing away the excess of glycerine by immersing the glycerinated tissue in sterile saline (one or several changes) or in glucose broth, after which small transplants (6 to 8 mm.³ approx.) were inoculated subcutaneously into mice, and the number of progressively growing tumours which resulted noted.

The table sets forth the results obtained in five experiments thus carried out, column 3 giving the time interval of the glycerine contact and column 8 the percentage of successful transplants, while subsidiary data is recorded for ulterior reference in the other columns.

No. of expt.	Parent tumour.	Glycerine treatment.		Transplantation into mice.			Percentage of successful "transplants."
		Duration of contact in hours.	Duration of subsequent washing.	No. inoculated.	Previous history.	No. of "takes."	
1	U.	24	5–10 mins. in saline.	6	4 "turn-outs" and 2 normal.	0	0
2	H.	2–4	½ hr. in saline.	6	Tumour-bearing	1	16
3	H.	2	¾ hr. in 3 changes of saline.	10	Normal, young.	1	10
4	U.	½	½ hr. in glucose-broth.	10	Normal, adult.	8	80
5	U.	¼	5 mins. in saline.	6	1 "turn-out" and 5 normal, young.	3	50

U., ulcerated; H., healthy.

Consideration of cols. 3 and 8 of this table shows that under the action of glycerine in vitro cellular vitality, or rather virulence (aptitude for in vivo growth), falls off rapidly beyond half an hour's contact, to be almost abolished in two hours. It is noteworthy, however, that up to half an hour's contact there is practically no loss of virulence of the tumour cells—i.e., no devitalisation of this particular type of tissue cell, the epithelial cell.



Relative Toxicity of Glycerine for Tissue Cells and Bacteria (Case of the Ulcerated Tumour).

Three experiments recorded in the table relating to the use of ulcerated tumour material concern us here. Such material it will be evident offered from the point of view of tissue cells (neoplastic) an ideal test material for the investigation of the question how far glycerine possessed—as presumptively established for leucocytes—greater toxicity for bacteria than for body cells.[1]

A typical experiment of this ulcerated series is recorded in the accompanying chart, which provides a complete representation of Experiment 4 (see table).

The upper portion of the diagram records the growth history of the mother tumour in a mouse during 52

days. The skin over the tumour became broken through and ulceration began, as indicated by the shaded areas on the tumour silhouettes, a few days previous to the forty-sixth day of charting. The ulceration, then, in this particular case, corresponded to a little over a week, during which time microbial infection of the tumour substance occurred freely—a time interval sufficient to render it in the ordinary course of events quite unfit for further experimental propagation. The mouse was sacrificed on August 22nd, 1926, the tumour excised, and a small portion of the non-necrotic shell (0·5 to 1 g.) transferred to a sterile test-tube containing pure glycerine. After a contact of half an hour, with frequent shaking to permit as thorough permeation as possible of the tissue by the glycerine, the tissue was removed and transferred for a quarter of an hour to a tube of glucose broth to wash away the excess of glycerine. Small pieces of the washed tissue were then transplanted into ten normal mice. The result is exposed in the remaining portion of the chart.

This latter reveals two facts of great interest. No deaths from septicæmia occurred among any of the experimental animals during the first week following transplantation, and there is recorded a remarkably high percentage of tumour "takes"—actually 80 per cent.

The fact of no deaths from septicæmia establishes the efficacy of the glycerine treatment in ruling out bacterial activity—in other words, of controlling bacterial virulence. This is the more remarkable in that the contact with the glycerine did not extend beyond half an hour—an interval of contact quite inadequate to kill bacteria of themselves, notably streptococci, staphylococci, *B. coli*, and enterococci, as we have shown elsewhere.[2] The action of the glycerine here, then, can hardly be other than that of an attenuating agent of bacterial virulence, in which case it enters into the same category of action as that established by Larson[3] in regard to the loss of pathogenic power of bacteria—*B. anthracis*, *T.B.*, *B. tetanus*, and pneumococci—by contact for short intervals—e.g., a quarter of an hour, with weak solutions of Na-ricinoleate, work which has of late been confirmed by Netter, Andre, Cesari, and Cotoni,[4] as concerns pneumococci and streptococci.

The second fact noted as worthy of interest—the high percentage of "takes" in the experiment—proves definitely that tumour cells had in no way lost their vitality under the experimental conditions concerned—treatment with pure glycerine during an interval of half an hour outside the body followed by washing away of the excess glycerine during another quarter of an hour—for they sprang forthwith into renewed reproductive activity and tumour formation when implanted into fresh animals.

A third fact revealed in this particular experiment, perhaps worthy of passing mention—although it cannot be stressed, as it was impossible for me at the time to follow it up further, owing to my departure for Egypt—is the seemingly increased virulence of the tumour cells following the glycerine treatment. This is indicated by the rather more rapid growth recorded for the daughter tumours ("glycerinated transplants" of the chart) during the first three weeks following transplantation, as compared with the initial growth history of the parent tumour over this same period. The rate of growth in the daughter tumours is, indeed, seen to be such that, by the end of the third week six out of eight of them had attained dimensions leading to skin tension and ulceration.

Summary.

Tissue cells of epithelial type are shown to possess a high degree of vital resistance to the action in vitro of pure glycerine upon them, cancer cells being utilised for the demonstration. It is established that these latter can support contact for half an hour with glycerine without their capacity for subsequent reproduction being affected—indeed, without t least sign of devitalisation.

Further, experiments are detailed which confir that glycerine is endowed with greater toxicity f bacteria than for tissue cells: in that, after glycer treatment, tumour cells, as representative tissue cel survive in vivo while bacteria disappear; and use h been made of this property to solve an importa problem in cancer research—namely, the successf propagation by transplantation of the ulcerat tumour.

A vast range of usefulness appears incidentally stand revealed for glycerine in surgery, especial as concerns plastic surgery and grafting operations.

I wish to thank Prof. C. A. Pannett for his symp thetic interest and enthusiastic encouragement this research, and others, carried out by me under h ægis at St. Mary's Hospital. It is a pleasure, beside to acknowledge my indebtedness to the Canc Hospital Research Institute for the tumour stra here employed.

Clinical and Laboratory Notes

A NOTE ON THE TREATMENT OF SARCOMATOSIS CUTIS AND MYCOSIS FUNGOIDES BY X RAYS.

BY ARTHUR WHITFIELD, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE SKIN DEPARTMENT, KING'S COLLEGE HOSPITAL.

I WOULD like to draw attention to a peculi phenomenon which may be observed as the res of the use of X rays in sarcomatosis cutis and myco fungoides. Eighteen years ago I had under r care a patient suffering from sarcomatosis cu whose history was as follows:—

CASE 1.—The patient, a medical man, aged 46, was sharply on the left breast by a tennis ball. A flat hæmato was produced and never disappeared, but changed character slowly until it became a brownish, tough infilt tion of the skin, apparently about half an inch in thickn After some months smaller but otherwise similar tumo began to develop on the head, trunk, and extremiti At first they only appeared at long intervals, but when came to me for treatment, two years after the blow, stated that he could find a new one, on the average, o a week.

A small tumour was excised to confirm the diagnosis, a the growth was found to be a typical, medium-sized, rou celled sarcoma lying in the deeper part of the true sk I recommended the use of X rays, and believing that original tumour was probably the parent of the other devoted myself first to this. A full pastille dose was gi unfiltered and the tumour disappeared leaving no ot mark but a slight atrophy and falling in of the skin. Sub quently the whole surface of the body was worked o with pastille doses, spaced appropriately and with sm intervening periods of time as would, it was believed, av too severe a damage to the patient's general health.

The result of this treatment was most striking; ev tumour disappeared and the patient enjoyed perfect hea for the next five years. He then returned to me, dur the war, with some recurrence on the skin of the ne accompanied by enlargement of the cervical glands. I unable at that time to carry out the treatment myself, sent him elsewhere to receive his X rays, and since t time I have lost sight of him, though I am afraid that probably died of his disease.

The striking feature of the case lay in the fact th whereas, before he underwent treatment for primary growth, he was developing fresh tumours the rate of one a week, no fresh tumours develop after the first pastille dose, and some of the smal ones involuted before they were treated local This peculiar behaviour of the tumours natura remained in my memory.

CASE 2.—On March 12th, 1925, I was asked to se maiden lady, aged 60, in consultation with Dr. Raym Streatfeild. The history of her eruption was somew

definite. She had suffered from eczema as a child and had covered, but since then she had been troubled, from me to time, with slight recurrences. The actual disease r which I saw her had probably begun on the scalp two ears before.

In the autumn of 1924 she was under the care of two rmatologists, one of whom had not considered the question mycosis fungoides, while the other, although suspicious, d been unable to find sufficient evidence for a firm diagnosis. hen I saw her six months later her condition was a assical example of mycosis fungoides and was advancing ith extreme rapidity. The scalp was covered with red, filtrated patches, partly excoriated and crusted, the face as almost wholly involved in a thick infiltration, and the hole of the trunk and the extremities with the exception the palms and soles were covered with marked infiltration ranged in the characteristic fantastic, polycyclical patterns. ching was intolerable and the patient's general condition as very bad.

In agreement with Dr. Streatfeild, I decided to give her ll doses of X rays. I pointed out that the result of her ndition might well be fatal from a general toxic absorp-n, but that the disease was in itself fatal and that death sulting from the X ray treatment would be easier by far an that occurring in the usual course of the disease. cordingly, on the same day full pastille doses, five in mber, were given to the top of the head, both sides of the e, and the upper parts of the shoulders behind. One week er five further full pastille doses were given to the nape the neck, both clavicular regions and both breasts five hes below the clavicular areas. At my suggestion, also, . Streatfeild gave her the first of a proposed series of podermic injections of sulfarsenol.

A week later (March 26th) I saw her again. She was then nfined to bed and apparently moribund, with a very weak lse, only just conscious, and taking very little nourish-nt. The areas irradiated on the first occasion were owing some improvement while those treated on the second re unaltered. An extraordinary change had, however, ken place in the areas not yet treated, and especially in se on the abdomen and the lower parts of the back and ttocks. These had all swelled up and become violently lamed, the horny layer being lifted off by a profuse serous charge. Owing to the grave condition of the patient was resolved not to continue with either the irradiation the sulfarsenol.

After a week in this condition the patient rallied slowly, parts first X rayed cleared up entirely, then the second ies followed suit, and finally all the rest of the eruption derwent complete involution with exception of a small tch, one inch across, on the outer side of the middle of right thigh. Her health improved rapidly so that she s able to get up and go down to the country for a holiday. On May 20th, two months after the last treatment by rays, I saw the patient again and her condition was as ows. The scalp was normal in colour, though, of course, d, and the only visible abnormality was some scaling embling an exaggerated scurfy head. The face, the trunk, l the whole of the extremities with the exceptions ntioned below were apparently quite normal, showing e, silky skin. On both buttocks, especially the right, re was some ill-defined scaling showing no particular tern and no infiltration beneath. On the right thigh re was still the single infiltrated, brownish patch about inch across. A full pastille dose was given to this and to right buttock.

The subsequent history of the second case is interest-. Not very long after her apparently complete overy from her disease mental symptoms began develop, and these progressed somewhat rapidly til the patient was in a condition of dementia. e was then placed in an appropriate home in which died nine months after the time when I first w her, without any reappearance of symptoms of cosis fungoides. A well-known alienist who saw her s of opinion that the mere curing of very wide-ead dermatosis, not necessarily by such drastic ans as X rays, was not infrequently followed by ere mental symptoms.

The point of interest in these two cases, more striking the second than in the first, is the remote effect he X rays. The violent reaction in the untreated ts of the eruption suggests that cytolytic products m the irradiated areas reached the rest of the ease by means of the circulation and there set up igestive process finally resulting in the removal of infiltration. Whether there is anything in my a of treating the earliest lesion first I am unable say, but I suggest that in treating such cases it l be well to treat part, and possibly preferably the oldest part, with the greatest doses that the skin will stand, and then to hold one's hand and watch the result on the untreated lesions.

Finally, I may emphasise the fact that I do not claim to have cured either of these patients. I have, however, the record of one case of mycosis fungoides in which my clinical diagnosis was confirmed by the late Dr. Colcott Fox after microscopical examination by both of us, and this patient, after being cleared by means of X rays, lived without relapse for a great number of years, finally dying of apoplexy when more than 70 years of age. It appears, therefore, that it is justifiable to take great risks in the endeavour to cure patients of a disease which is otherwise invariably fatal, and in its terminal stages is accompanied by hideous suffering.

A CASE OF
TOXIC NEUROLABYRINTHITIS
FOLLOWING THE INDUCTION OF LABOUR BY QUININE.

BY F. PEARCE STURM, M.CH. ABERD.,
AURIST AND LARYNGOLOGIST, LEIGH INFIRMARY, LANCASHIRE.

Tinnitus and vertigo are common enough in predisposed individuals who take large doses of quinine, but they usually disappear with the discontinuance of the drug or the consumer's habituation to it. In the following case three doses were followed by a neurolabyrinthitis which for several years has been progressive.

The patient, aged 32, states that while an in-patient in a local hospital for women in 1924 three attempts to induce labour by the administration of quinine and castor oil were made at intervals of a week, the third attempt being successful. After the first two doses she suffered for 24 hours from severe tinnitus and vertigo, which were, however, transitory. After a third dose, which was followed by labour, the tinnitus became permanent, and has remained so for three years. It varies in intensity; it is worse at the menstrual periods, which are regular; recently it has become occasionally intolerable. When at its worst it is accompanied by vertigo, the last attack of which caused her to fall in the street.

The otoscopic image is normal in both ears; the Eustachian tubes are patent; the nose and nasopharynx free from obvious disease. The caloric labyrinth reactions are normal and equal on both sides. She has perfect hearing so far as this can be tested by clinical methods. Rinné's test is positive in both ears. The upper and lower tone limits for air-conduction as tested by forks, whistle, and monochord are unshifted. She states that her hearing is now often painfully acute. As tested by Bárány's noise-box there is evident dysacusis, but this is so common in sensitive patients with normal ears that its clinical significance is negligible. The only definite functional abnormality is a slight shortening of bone-conduction on both sides (five seconds for C 128).

In the absence of any personal or family history of previous ear, nose, or throat trouble, this case must be regarded as a toxic neurolabyrinthitis due to quinine. Otosclerosis is excluded by the fact that the lower tone limit is unshifted. Even in the earliest stages of otosclerosis, previous to any functional disability appreciable by the patient, a shortened air-conduction for low tones is always demonstrable. I do not know the quantity of quinine taken by this patient, but am informed by my gynæcological colleague, Dr. L. A. Burt, that doses of as much as 10 gr. of the sulphate of quinine may be given for the induction of labour. As an otologist who for many years, following Charcot's practice, has treated "aural vertigo" with maximum doses of ½ gr., 10 gr. seems to me to be an excessive and potentially dangerous quantity.

ADDENBROOKE'S HOSPITAL: PROPOSED ENLARGEMENT.—It has been decided to place a new block in the front of Addenbrooke's Hospital, Cambridge, in line with the front of the out-patients' department. The new block will contain on the ground floor a board room and a lecture room, and on the first floor the wards for children. In the main building new wards are to be added; the cost of the work is estimated at £37,400.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT EDINBURGH.

(*Continued from p. 285.*)

SECTION OF SURGERY.

WEDNESDAY, JULY 20TH.

THIS Section met, with Prof. D. P. D. WILKIE in the chair, to discuss

TUBERCULOUS DISEASE OF THE KIDNEY.

Sir JOHN THOMSON-WALKER (London) said that in 1900 the mortality from nephrectomy for this condition was 25 per cent., whereas to-day it was 3 per cent. or less. This advance was due to (1) an increased knowledge of the pathology of the disease, (2) improved technique, (3) earlier diagnosis, and (4) the introduction of the cystoscope and ureteral catheterisation. There were three types of tuberculous disease of the kidney—miliary tuberculosis, tuberculous nephritis, and renal tuberculosis. The first two did not concern the surgeon. In renal tuberculosis the first change was at the apex of the pyramid where ulceration took place; cavity formation occurred later, and later still there was thickening of the wall of the calyx. If secretion was maintained the result was tuberculous hydronephrosis leading to suppression of secretion and to caseation. The symptoms included frequency of micturition, pyuria, hæmaturia, renal pain, and some fever. In spontaneous cure the tuberculous kidney might heal by scarring of the ulcerated pyramid. The cavity might be shut off by fibrous tissue (closed renal tuberculosis); the symptoms disappeared and the condition was only discovered at careful medical examination or post mortem. The urine might yield pus, the kidney might be palpably enlarged, or a shadow might be seen in the radiogram.

Tubercle bacilli were present in the urine of 80 to 90 per cent. of young adults with typical symptoms. They might not be found owing to their scarcity or because they were intermittently present, or because the cavity was closed and shut off from the renal pelvis. In such cases the presence of tuberculous lesions elsewhere, or cystoscopic examination, would lead to a diagnosis. On cystoscopic examination the ureteric orifice was drawn up and catheterisation of the ureters might be difficult; the bladder might be opened and an attempt made to catheterise the ureters direct. Prof. A. Fullerton had devised a method of exposing the ureters extraperitoneally at the pelvic brim and there examining them, opening the lumen for catheterisation. On account of its progressive nature, tuberculous disease of the kidney should be treated by nephrectomy without delay where the second kidney was healthy and there was no contra-indication. At operation the ureter might be divided and cauterised at the lower pole of the kidney, or might be removed by dissection from above or from the iliac fossa. Or the ureter might be left and the patient kept under observation for a year when, if trouble arose, it could be removed extraperitoneally. The wound should be closed completely without drainage in order that the risk of persistent sinus formation might be minimised. In his series the operative mortality was 2·5 per cent., and while 60·3 per cent. of the patients were completely cured, 17 per cent. had died later from various causes. In the postoperative period tuberculin had been administered in small doses.

Dr. A. ROLLIER (Leysin) described heliotherapy as a subsidiary factor in the treatment of renal tuberculosis, and nephrectomy as the only rational method in unilateral disease. Where there was pyuria with tubercle bacilli in the urine delay was dangerous because of infection of the bladder. In the preoperative stage, when the patient was weak, a course of heliotherapy would considerably improve resistance. In the postoperative stage it would prevent a flare-up of quiescent lesions elsewhere which the temporary disturbance of the operation might have occasioned. It might also hasten cicatrisation of the ureteral stump. In chronic and gaping broken-down wounds heliotherapy, well directed, would encourage healthy granulation and eradicate tuberculous infection. In bilateral renal tuberculosis it would assuage pain, encourage auto-immunisation, and bring a feeling of well-being not otherwise obtainable.

Prof. ANDREW FULLERTON (Belfast) said that the questions to be faced were: (1) Is the lesion unilateral? and (2) is cure possible without operation? Of 158 patients with tuberculosis of the bladder 87 were males and 71 females. In 141 cases evidence of involvement of the kidney was found, and in seven of these (5 per cent.) the condition was clinically bilateral. In 29 of the 87 males (33 per cent.) deposits of tubercle were present in vesiculæ, prostate, or epididymis. A history of previous tuberculous lesion was present in 26 per cent. of all the cases; a focus was found in 15 per cent. In 73 cases nephrectomy was performed, with five deaths, all of which occurred in the first 35 cases. Of the 68 survivors, 55 had been traced; 15 had since died, four of them, after long periods of relief, from causes other than tubercle. Unsuspected renal tuberculosis was rife among phthisical patients, in whom there might be no tissue destruction. Ureteral catheterisation might upset the sphincteric action of the ureter and permit contamination of a healthy renal pelvis. After nephrectomy the stump of the ureter near the bladder might be slow to heal and might be dealt with from an incision in the iliac fossa extraperitoneally. Of 41 out of the 68 patients not treated by operation the after-history had been traced; 26 (over 63 per cent.) were dead, and only two of the others had since had relief from symptoms by a process of auto-nephrectomy—i.e., by conversion of the ureter into a solid cord.

Mr. HENRY WADE (Edinburgh) said that in the investigation of a suspected case of renal tuberculosis it was necessary to determine (1) the kidney involved, (2) the state of that kidney and its fellow, and (3) the actual presence of another kidney. Tuberculosis of the kidney could be diagnosed without the presence of tubercle bacilli in the urine, making use of the preliminary radiogram of the renal region which might demonstrate calcareous deposit. The history, the presence of pyuria without demonstrable organisms and the diminished capacity of the bladder were significant. Cystoscopically, the presence of the golf-hole ureter was diagnostic. In the pyelogram the presence of cavitation at one part with normal outline elsewhere was typical of renal tuberculosis. If the ureteral catheter stuck after entering the ureter for only 1 or 2 cm., the taking of a ureterogram would demonstrate the typical irregularly dilated appearance of the tuberculous ureter and similarly the normal contour of the photograph of the opposite side would demonstrate a healthy kidney the. Spontaneous cure of renal tuberculosis never occurred, and a healed tuberculous lesion of the kidney had never been seen post mortem. The treatment was nephrectomy, but if by heliotherapy the general state could be improved in the preoperative period the danger of general infection later would be diminished. Irritability of the bladder might persist after nephrectomy owing either to lack of mobility of the layers in the wall of the bladder at the site of a healed ulcer or to persistent single ulcer in the summit of the bladder. In the latter case persistent single ulcer might be excised with complete cure of frequency.

Mr. J. F. DOBSON (Leeds) pointed out that examination was difficult in advanced tuberculosis of the bladder, and to obtain information as to which was the diseased kidney it was essential to catheterise the ureter. Fullerton's method was especially useful where cystoscopy failed; both ureters could be exposed and examined for thickening and mobility and a sample of the secretion could be obtained.

Mr. BERNARD WARD (Birmingham) said that the disease started at the apex of the pyramid and the upper papillæ were more often involved than the lower. The cystoscopic appearance of the tuberculous ureteral orifice was characteristic, but in addition the estimation of combined renal function, chromocystoscopy, and thorough examination of the urine should lead to a definite and accurate diagnosis.

Mr. ERNEST WARD (Paignton) said that in pulmonary tuberculosis there were often renal symptoms which usually disappeared under a hygienic régime. After nephrectomy for unilateral renal tuberculosis there was sometimes recurrence of tubercle in the other kidney or the lungs or generalised tuberculosis. After operation hygienic conditions and the use of heliotherapy were valuable.

Mr. TEMPLE MURSELL (Johannesburg) spoke of the necessity for calling in a cystoscopist whenever a patient was suspected of renal tuberculosis; the diagnosis could then be rejected or confirmed. In Johannesburg there were excellent facilities for heliotherapy, but ultimate cure by this means was impossible, though the late results of the cases operated on were good, and the benefits of preliminary treatment with sunshine were very great.

Mr. GORDON CRAIG (Sydney) referred to two cases treated by tuberculin and general hygienic measures without operation which had remained cured for 15 years. This showed the advantages of climatic conditions and heliotherapy. He mentioned the value of sacral anæsthesia with novocaine in cystoscopic examination of the bladder where there was much irritability.

Sir JOHN THOMSON-WALKER, in reply, said that in no histological examination of so-called healed tuberculous lesions of the kidney had he failed to note evidence of round-cell systems indicating persistence of the condition. Early in the disease the ureter might still be mobile and supple although transmitting infected urine, and therefore in Fullerton's method of examining the ureter extraperitoneally it was necessary to open its lumen and withdraw a sample of the urine. In advanced renal tuberculosis it was impossible to take away the infected perirenal fat and thus completely remove the infected area, but in only 6 per cent. of cases had he found it necessary to remove later a ureter left at the original operation.

Mr. W. RANKIN (Glasgow) read a paper on

Primary Diaphysectomy in Osteomyelitis.

In osteomyelitis, he said, the periosteum of the affected bone was lifted up and the epiphyseal cartilage separated. A portion of bone died and formed a sequestrum which, after a long process of natural separation, was extruded. The process occupied many months, during which there was a constant danger of pyæmia and a general deterioration of health. In diaphysectomy the bone which was doomed to death and sequestrum formation was removed rapidly and cleanly by operation, and new bone was afterwards laid down evenly and soundly, replacing the involucrum of Nature. The operation should not be performed on patients over 12 years of age; the bones most frequently operated on were the humerus, the femur, and the tibia. Where a long bone had been involved an internal glass rod splint was used to maintain the natural length of the limb. A series of cases was shown.

Mr. ROBERT KENNON (Liverpool) said that tenderness at the site of pain in a bone, persisting over 12 hours and accompanied by fever, indicated osteomyelitis and the need for operation. X rays would not demonstrate any change in the bone where pus formation alone, without decalcification, had occurred.

Mr. MARCUS MAMOURIAN (Ashton-under-Lyne) did not favour diaphysectomy in early cases where simple opening of the medullary cavity would suffice. In the later neglected cases the operation yielded brilliant results. A bone-graft could be used with advantage instead of an inert internal splint.

Mr. ROBERT OLLERENSHAW (Manchester) had done diaphysectomy chiefly where one of two bones was infected. In such cases extension and splinting had been the main standby in preserving the line and length of the new shaft.

Mr. RANKIN, in reply, said that among 14 cases there had been only two deaths. The technical difficulties in twisting the diaphysis free from the epiphyseal plate were slight and the plate was never damaged. In the after-treatment, in addition to the internal glass rod, extension devices—e.g., callipers—were used, besides plaster-of-Paris and other splints. After-care was of primary importance in securing a sound result.

THURSDAY, JULY 21ST.

The next session of this Section was devoted to a discussion on the

PLACE OF SURGERY IN THE TREATMENT OF TOXIC GOITRE.

Mr. T. P. DUNHILL (London) said that though many cases of toxic goitre fell into definite groups, practically every type of histo-pathological condition might be found somewhere in a diseased thyroid gland. There was a tendency to multiply types and subdivisions, but the different types were related, and it would ultimately be found that the differences were only in degree. He would refer to the following forms of goitre: (1) primary Graves's disease; (2) secondary Graves's disease, early; (3) colloid; (4) late, which was largely fibrous with small adenomatous nodules, little exophthalmos, and marked nervous and cardiac disturbance; (5) unilateral adenomatous enlargement in secondary toxic goitre; and (6) single adenoma in secondary toxic goitre.

In exophthalmic goitre it was easy to recognise clinically a primary type (symptoms and goitre together) and a secondary type (goitre first, symptoms later), but it was hard to say where the primary type ended and the secondary type began. Histopathologically, also, a primary and a secondary type were recognisable, but some cases which histopathologically were undoubtedly secondary would clinically have been considered primary. There might be great differences between examples of the secondary type, and some of them approached very closely to what was generally called toxic adenoma. A case of primary Graves's disease had well-defined features; an early secondary case was scarcely distinguishable from it. In the late secondary case exophthalmos had become less, the nervous phenomena were less obvious, but cardiac changes were more marked. Working backwards, the toxic adenoma was well recognised, but sometimes there was more than one adenoma and a gland might be bilaterally symmetrical, and the nodules in it scarcely recognisable as adenomata, so that the whole gland approached the type of late secondary exophthalmic goitre.

At puberty there was a tremendous call on the function of the thyroid gland. To meet it there was temporary hypertrophy. Involution should occur after the demand had been successfully met; if it did not, then a colloid goitre remained. The stimulus from outside the gland produced the pathological changes, but the changes thus produced in turn caused the manifestations of the disease. In exophthalmic goitre the stimulus might be subconscious, psychic, or traumatic, or possibly from focal sepsis or deficiency of available iodine. Such a stimulus, acting on the normal gland, caused primary exophthalmic goitre. Where it acted on a colloid goitre only the areas between the vesicles were able to respond. In the primary case the signs and symptoms preceded the goitre. In the secondary type the other signs and symptoms followed the occurrence of a colloid goitre. Both types showed prominent eyes, a hot skin, tremor, and a rapid pulse, and they followed a similar course. In the third decade the colloid goitre of puberty became nodular though still symmetrical. The factors which in a younger patient produced frank exophthalmic goitre might come into

action at any time, but when they were directed against an old fibrotic goitre the areas able to respond were small and the result was late secondary Graves's disease. The pathological change might be scattered throughout the whole gland or limited to one lobe or portion of a lobe, in which case a single adenoma might be formed, removal of which would free the patient from her symptoms.

The place of surgery in the treatment of toxic goitre varied in each of the conditions discussed. Out of 273 patients operated upon, 107 had suffered for four years, 77 for more than six years, 53 for more than ten years. While the patients were under medical care lying in bed disturbing features impossible to arrest had occurred, such as damage to the eye, glycosuria, mania, loss of weight, and auricular fibrillation. The economic factor was important and it was impossible medically to restore these cases to an industrial plane. Surgical intervention varied with the type of the disease. In a primary case operation should be delayed, for many people with slight symptoms could be piloted medically back to health. After six months' persistence of the disease —unless the patient led a sheltered life—surgery must be considered. In primary and secondary Graves's disease with auricular fibrillation there should be no delay beyond the time necessary to get the patient into the best condition for undergoing the operation. When symptoms appeared in association with long-standing goitre, it was a waste of time to delay operation, and neither rest, medical nor X ray treatment would avail, whereas removal of the adenomatous mass would cause disappearance of the symptoms. In preparation for safe operation focal sepsis should be attended to, the pulse-rate should be lowered by rest in bed and iodine medication, and the extent of the operation should be graded. In cases of grossly incompetent heart, coöperation was essential between physician and surgeon. The death-rate varied according to the type of case operated on. For Graves's disease, excluding toxic adenoma, he had found that it was 2·8 per cent. Tetany and damage to the recurrent laryngeal nerve had occurred. To make the operation effective, enough gland substance must be removed to eliminate the toxic effect of the secretion, always bearing in mind the physiological needs of the body. Exophthalmos would largely disappear. In cardiac failure with auricular fibrillation, 87 per cent. of patients had been restored to health with normal cardiac rhythm as a result of operation. Glycosuria had disappeared and dropsy had been completely abolished by the resumption of normal urinary output. Patients who had suffered severely from exophthalmic goitre never returned to their previous condition, but they were a great deal nearer normal after operation, and almost all of them could take up their work and enjoy life once more. In a chronic case, with the heart and nervous system flooded with toxic secretion, sometimes for years, the organs quickly showed relief when this toxic secretion was suddenly reduced by four-fifths, but it was unreasonable to expect that their complete recovery should be other than gradual, and their capacity to withstand strain might never be quite complete.

Prof. G. R. MURRAY (Manchester) said that toxic goitre included all classes which gave general symptoms due either to excessive secretion or changed secretion. In the primary case toxic symptoms preceded thyroid enlargement; in the secondary case the enlargement preceded the symptoms. In thyrotoxic myocarditis the only chance of recovery was by operation, and advanced cardiac œdema was not a contra-indication to operation. The advantages of operation were found in the time saved, the rapid recovery, and the prevention of myocarditis.

Mr. THURSTON HOLLAND (Liverpool) claimed that the primary treatment of early cases of exophthalmic goitre should be by means of X rays, even without any other therapeutic measures. The only disadvantages seen in a large number of cases had been the occurrence of a burn and the risk of producing myxœdema. Early cases subjected to X ray therapy might be completely cured, and later cases should be given a chance.

Prof. R. E. KELLY (Liverpool) said that intratracheal ether anæsthesia in thyroid cases was of the utmost value. Pulmonary complications were very rare, and to prevent damage to the trachea in the passage of the catheter it was wise to X ray the part first. Warming the ether had no advantage as it was cooled in the tubing. In preparation for the anæsthetic, morphia should be used with care in case of maniacal idiosyncrasy. Similarly, the use of iodine might produce undesirable effects.

Dr. JOHN EASON (Edinburgh) said that fulminant cases of primary exophthalmic goitre were rare. In all cases complications could be anticipated and guarded against. With early diagnosis and supervision of individuals verging on the disease deterioration of organs could be allayed. A 5 per cent. operative mortality must be balanced against many years of fair living obtainable by those who were given careful medical supervision. Individual cases varied in their chance of recovery from operation and the operation in itself might not always prevent recurrence of symptoms. The preoperative period required careful handling and the preparation for preliminary minor operative procedures directed against focal sepsis in the teeth, &c., should be as thorough as for the major operation.

Sir WILLIAM WHEELER (Dublin) referred to a series of 82 cases, in 90 per cent. of which the patient had been subjected to medical and X ray therapy for years, and after remissions with increasingly severe crises had come to the surgeon. The only certain means of preventing relapse in toxic goitre was subtotal thyroidectomy, although 50 per cent. of cases showed considerable improvement with Lugol's iodine. X ray therapy was no guard against late relapse and death.

Mr. JOHN MORLEY (Manchester) said that surgical and radiological methods of treatment in the simple primary case caused improvement as contrasted with medical measures which did not. Surgery was more rapid than radiology. The preoperative régime under Lugol's iodine had greatly reduced the mortality. The operation to perform was seven-eighths subtotal thyroidectomy, and it was an advantage to give subcutaneous saline continuously throughout the operation.

Mr. A. J. WALTON (London) said that exophthalmos was a rare complication in colloid goitre and diffuse adenoma of the thyroid. X ray treatment in the preliminary treatment of exophthalmic goitre was useless as contrasted with its advantage in early carcinoma of the thyroid. Fibrosis did not occur after X ray therapy. Since the introduction of Lugol's solution in the preparation of the toxic case for operation there had been no operative mortality and the preoperative period of preparation had been limited in its extent.

Dr. L. A. ROWDEN (Leeds) said that in Leeds no case of toxic goitre reached the surgeon. Treatment was successfully carried through with X rays and no undesirable sequence such as burns had arisen. The results were especially satisfactory in cases with little enlargement of the thyroid but a high basal metabolic rate.

Dr. STARR (Toronto) considered that prolonged X ray treatment had no effect in preventing cardiac deterioration. In a series of 253 operations for goitre only 23 were on patients without toxic symptoms.

Mr. C. A. JOLL (London) said that exophthalmos was never present in true toxic adenoma. Lugol's solution could be used with advantage in cases both of exophthalmic goitre and toxic adenoma. At operation it was advisable to remove nine-tenths of the gland and when a small portion of gland-tissue was left posteriorly there was no danger of damage to the recurrent laryngeal nerve.

Mr. DUNHILL, in reply, agreed that it was undesirable to operate on early cases of Graves's disease. In the treatment and management of such cases it was

necessary for the surgeon, physician, and radiologist to work in close coöperation.

Sir ALMROTH WRIGHT (London) read a paper on the

Rational Treatment of Infected Wounds.

During the late war, he said, wounds were found in a state comparable to those occurring in the Middle Ages. Certainly wounds seen in civil hospital practice before the war held no comparison. Wounds reaching hospital in the war area contained material resembling fæcal matter, and every type of organism could be isolated from them. By the use of an adapted glass tube called a lymph leech, serum was obtained from such wounds, and on examination was found to contain the streptococcus alone. Normal serum had antitryptic power, and organisms growing in serum neutralised this antitryptic power and were termed serophytes. The pus and serum obtained from these grossly infected war wounds were completely lacking in antitryptic power; the organisms growing in them had produced trypsin which had overcome the resistance of the serum and had permitted digestion of the tissues. The end-result was a medium ideal for the nourishment of organisms. In the examination seriatim of layers of pus from a wound, the superficial layer contained a heavy infection of all kinds of microbes, whilst in the deeper layers of pure serum the streptococcus and staphylococcus alone were found. A heavy infection would allow organisms to grow in the blood because of the destruction of the antitryptic power of the serum. But by hole-and-corner methods of infection a less heavy infection would produce a similar effect because organisms hidden in odd corners of a wound had to deal with a smaller area of resistance from the serum, and thus more readily produced auto-digestion of surrounding tissue. The gangrene bacillus grew with difficulty in normal blood but readily in wounds, especially where a tourniquet had been applied or physical exertion had immediately preceded the wound. Always where normal alkalinity had been reduced there was a heavy infection of gangrene. Cases with acid intoxication had amazing recuperative powers after the administration of alkaline fluid. Experimentally, growth of *Bacillus welchii* occurred in blood to which antiseptics had been added. The antiseptic combined more readily with the albumin of the medium than the encapsuled albumin of the microbe and had therefore no value in safe concentration. The ideal combatant to microbic growth was blood serum, and a wound flooded with normal serum quickly became sterile. Dakin's solution produced a delayed out-pouring of serum on being applied to the surface of a wound. Experimentally, it had been shown that 5 per cent. salt solution would produce a quicker and greater outpouring of serum when applied to the surface of a wound, and application of this solution was the most satisfactory of all methods for the treatment of wounds.

FRIDAY, JULY 22ND.

At the third session of this Section there was a discussion on

CHRONIC APPENDICITIS.

Mr. WILFRED TROTTER (London) said that appendicitis first became known to surgery as a curable form of abscess in the right iliac fossa. Later in its milder forms it became known as a pathological condition which never completely returned to the normal. This discovery led to the interval treatment of appendicitis. An appendix removed at operation in the interval state might show: (1) unmistakable residual signs of recent inflammation, either ready to flare up or with fibrosis and obliteration of the appendix lumen; or (2) normal appearance in length, colour, and lumen; or (3) it might be long but fixed at some part and with a non-uniform lumen and spongy mucosa. It might contain inspissated fæcal matter. Furthermore, the ileo-cæcal glands were sometimes enlarged and this enlargement was often associated with a train of symptoms cured by appendicectomy.

The symptoms of quiescent and chronic appendicitis were indistinguishable. The pathological processes occurring were: (1) septic absorption, and (2) disturbance of motility and secretion. In the first of these the enlarged glands in the ileo-cæcal region demonstrated a path of septic absorption similar to that occurring from an infected tonsil. This factor of enlarged glands in relation to the appendix produced a train of symptoms bearing a direct relationship to the youth of the patient. Many attacks of supposed appendicitis in children were really due to acute inflammation of these glands, and tuberculosis in the glands was common, judging by the frequency of calcareous deposit in them. In the differential diagnosis, however, ureteral stones and upper abdominal conditions, such as cholecystitis, must be remembered. In children the effects of septic absorption from an appendicular focus might include osteo-arthritis, chronic pustular affections of the skin, and toxic conditions of the heart. If the appendix was unable to get rid of its fæcal contents its secretory activity must be interfered with. The gastro-intestinal tract was a unit and if the motility of the appendix was disturbed there were distant effects in the colon and stomach. This was borne out by the frequency with which other abdominal symptoms were found in association with the pathological appendix, and every abdomen opened for appendicectomy should be generally explored. Cases could be grouped into: (1) the obvious straightforward appendix case—the child; (2) the case suggestive of other abdominal or pelvic complications—the adult; and (3) the case with abdominal trouble not easy to place especially where there was a possibility of malignant disease. In the two last groups the incision must be planned to permit satisfactory exploration of all abdominal viscera.

Mr. J. W. DOWDEN (Edinburgh) said that where a history was given of symptoms in the classical order—umbilical colic, then vomiting, then right-sided pain—the diagnosis of appendicitis was straightforward, but difficulties arose when this information was not obtained. A significant history in children was lack of appetite, listlessness, and inability to wear a waist-belt because of iliac pain. Tenderness might be at the classical point or to the left of the umbilicus or over the pylorus, but by judicious palpation with both hands the main tenderness would always be found in the right iliac fossa with relief at the other point where the case was one of true appendicitis. Tuberculous ileo-cæcal glands gave a syndrome of gradual onset, diffuse tenderness, and usually demonstrable enlarged glands in the neck. In adults incipient hernia with pain at the internal inguinal ring might simulate appendicitis. The visceroptotic female with a variety of tender areas in the abdomen, with discursive pain, and gurgling colon, often obtained relief in the recumbent posture. She was of the type which operation might convert into the "abdominal woman." Appendicular dyspepsia might closely simulate duodenal ulcer and even produce melæna, but was distinguishable by the intermittence of the symptoms and their variation from day to day.

Mr. VICTOR BONNEY (London) said that the right ovario-pelvic ligament passed from the uterine appendage in relation to the cæcum and appendix. Through this relationship lesions of the appendix, appendages, and ovary might react on one another and give rise to pain. Chronic appendicitis reacting on the pelvic organs gave rise to symptoms in them, and vice versa. An increasing number of ovarian blood-cysts were now seen which were due to intra-ovarian menstruation with an accumulation of blood in the ovary. Severe pain was caused every time the blood was poured out and in the later stages a large adherent mass was formed. In early cases where ovarian enlargement could not be made out the right-sided pain might simulate appendicitis. The pain, however, always recurred immediately before the menstrual period. There might be signs of peritoneal irritation, but the toxæmia and furred tongue of appendicitis were always absent. With retroversion

of the uterus, there might be pain on both sides. Pain on one side in excess would indicate a lesion of the bowel, glands, or appendix in relation to the stretched ovario-pelvic ligament.

Mr. A. J. WALTON (London) said that one attack of appendicitis rendered the patient liable to future attacks, usually of increasing severity. Primary chronic appendicitis was discredited except in the process of fibrosis, which was normal in older people or accompanied visceroptotic and pelvic disorders in women. In a large series of cases the area of hyperæsthesia most commonly found was in the groin, and often erosion of the mucous membrane in the stomach was noted in association with appendicitis. The pathological appendix was one in which either distension, pus, or stenosis could be demonstrated. In a series of cases in which operation was performed in the upper abdomen, appendices of healthy appearance were left, and in only 0·2 per cent. did attacks of appendicitis afterwards occur.

Mr. H. N. FLETCHER (Brighton) referred to the value of following up cases; many instances were brought to light in which appendicectomy had failed to relieve symptoms. A history of a classical primary attack of acute appendicitis was of the utmost value in diagnosing chronic appendicitis in cases with the right-sided pain syndrome. The removed appendix should always be examined histologically to confirm the diagnosis. Examination of the urine was essential to exclude a lesion of the kidney. Abnormal bands such as Lane's and Jackson's were sometimes better left alone and in the after-treatment of the visceroptotic patient whose appendix had been removed postural education and abdominal exercises were useful.

Prof. A. H. BURGESS (Manchester) advocated careful examination and comparison of the two iliac fossæ as regards the site of tenderness and grade of hyperæsthesia. In the straightforward case it was advantageous to examine other viscera, so as not to miss some other condition, as yet quiescent. This was especially necessary in older patients in whom malignant disease of the colon might occasionally be discovered before the onset of symptoms.

Prof. ANDREW FULLERTON (Belfast) said that in hydronephrosis and cysts of the kidney, and occasionally in renal calculus, there might be no blood in the urine. In addition to radiography, useful information could be got from an estimate of the specific gravity of the ureteral samples of the urine. Unilateral diuresis with low specific gravity was found in tuberculous kidney, renal calculus, and cysts of the kidney. In hydronephrosis a higher specific gravity due to inspissation was found. This method of examination was useful in the differential diagnosis of pain simulating chronic appendicitis.

Mr. G. H. COLT (Aberdeen) said that on palpation over McBurney's point in cases of chronic appendicitis a fine crepitation might be felt, quite distinct from a gross cæcal gurgle. This crepitation was typical of chronic appendicitis. Where adventitious bands were present their division at operation would prevent the possible occurrence of intestinal obstruction later.

Mr. TEMPLE MURSELL (Johannesburg) regarded Rovsing's sign as very useful in the examination of patients with right-sided pain. It depended on the production of pain in the right side of the abdomen over the appendix as a result of pressure in the left iliac fossa, and it was diagnostic of appendicular lesions.

Mr. M. MAMOURIAN (Ashton-under-Lyne) said that the incision for operation on a case with right-sided pain should be planned according to individual requirements, which might or might not point to more extensive exploration.

The PRESIDENT (Prof. D. P. D. WILKIE, Edinburgh) said that an excessive number of operations had been performed for chronic appendicitis, and diagnosis in this type of case had become less accurate than in other branches of medicine. The patient willing to have an operation and satisfied with such a diagnosis hesitated to spend time and money in the necessary investigation which would make it more accurate. Patients must be educated to the essential advantage of spending time on such investigation. The value of X rays in the diagnosis of chronic appendicitis was doubtful, but X rays were important in excluding associated lesions in the stomach or duodenum. Palpation of the abdomen while the patient was undergoing screen examination in the X ray room gave useful information about the site of tenderness.

Mr. TROTTER, in reply, remarked on the necessity for thorough preliminary examination of the patient both by clinical and laboratory methods. Chronic appendicular trouble was most rife in children, and appendicectomy might be limited more and more to the young. Tenderness in the right iliac fossa varied in degree with the type of patient. In the systematic physical examination of healthy students visceroptotic defects were commonly discovered. Diseases were due to infections and injuries and not to variations in anatomical contour.

Mr. ALEXANDER MACLENNAN (Glasgow) read a paper on

Burns.

The pain following a burn, he said, was severe except in those advanced and extensive injuries where an ominous quiet preceded death. In children light chloroform inhalation was safer than morphia as an analgesic. In the treatment of the burned surface the continuous bath was useful; in its absence, coverings of sterilised waxed paper were an excellent protective. Picric acid dressings were analgesic and gave protection by coagulating albumin. In the treatment of shock repeated doses of opium and alcohol were of value, and body-fluids must be replaced with saline. If sepsis should arise there was a danger of septic pneumonia, and because of this danger, where grossly damaged tissues were present, early amputation of a severely burned limb or excision of a burned surface was to be recommended. Skin-grafting was useful to hasten healing and prevent contracture, but there must be careful preparation of the field where Thiersch or Wolfe grafts were used. Tunnel grafting could be used at an earlier stage and consisted of burying narrow grafts under the surface; in ten days the covering crust could be removed and a large percentage of "take" might be expected. Areas slow to epithelialise could be usefully stimulated with scarlet red. In the treatment of late contracture it was necessary, before making use of a pedicle graft, to beware of persistent, though dormant, infection in scar-tissue.

Mr. W. C. WILSON (Edinburgh) described the following stages after burns: (1) shock, (2) acute toxæmia, (3) sepsis, and (4) healing. To meet those stages it was necessary in (1) to restore the normal temperature and protect from pain; and in (2) to prevent absorption of protein poisons from the burned area by causing coagulation; whilst in (3) an efficient coagulum protected against sepsis. A 2½ per cent. solution of tannic acid in sterile water applied as an hourly spray had been found of great value in the treatment of burns. The burned area was prepared under a general anæsthetic by carefully cleansing with methylated ether and snipping away all damaged tissue. The tannic solution was then sprayed on at hourly intervals and allowed to dry by exposure to air and heat. In a few hours a brown hard coagulum formed which gave complete protection from pain and sepsis. In 8 to 14 days the coagulum separated and the area was found to be almost completely covered with healthy epithelium. Where a case was seen late after severe toxæmia had produced exsanguination the most satisfactory measure was to give a transfusion of blood before dressing the burned area in the manner above described. The mortality following burns in a children's hospital was given as 37 per cent., but in a series of 37 cases treated by the tannic method there were only three deaths.

Mr. F. J. STEWARD (London) said that a burn must be thoroughly cleaned and sterilised before being dressed. A general anæsthetic was essential to give the surgeon time and opportunity for this cleansing.

EXHIBITION OF DRUGS, SURGICAL INSTRUMENTS, FOODS, AND APPLIANCES.

THE usual trade exhibition was opened in the Waverley Market Hall on July 18th. A brief notice of the more important exhibits is given below and will be concluded in the next issue of THE LANCET.

DRUGS AND PHARMACEUTICAL PREPARATIONS.

1. *General Drug Exhibits.*

[52] Anglo-American Pharmaceutical Co., Ltd. (Galen Works, Croydon), showed various preparations, including Huxley's witch-hazel jelly, preservative for the skin, and safeguard against midge-bites, sunburn, &c.; Huxley's dusting powder; Huxley's sal-antisepticus, a soluble antiseptic powder similar to liq. thymol co.; Huxley's glycerophosphate syrups; and "Colchi-sal"—capsules of colchicine methyl salicylate.—[63] The Anglo-French Drug Co. (238A, Gray's Inn-road, W.C.1) showed a series of special pharmaceutical preparations, including "Pharmasol Cuprum Radio-active," a non-toxic compound of colloidal hydroxide of copper with mesothorium bromide, for injection in cases of cancer; and "Orargol," a colloidal gold and silver preparation, in ampoules and solution, for general antisepsis, internal and external. At the same stand Modern Pharmacals, Ltd. (2, Calthorpe-street, W.C. 1), were showing the original Lehnhoff-Wyld Sulfarsenol.—[76] Armour and Co., Ltd. (Queen's House, Kingsway, W.C. 2), had a display of their "Glanoid" endocrine and ferment preparations in tablet, liquor, and ampoule forms. Special attention was drawn to specimens of glands preserved in their natural colours. A new silky "non-boilable" catgut ligature was also shown.—[44] Boots Pure Drug Co., Ltd. (Station-street, Nottingham), showed a selection from their ever-increasing issues of modern preparations and fine chemicals, compressed tablets, and surgical sundries. These included "Stabilarsan" (Boots); "Thiostab" (Boots), for chronic metallic poisoning; "Bismostab" (Boots), a suspension of metallic bismuth in isotonic glucose; "Sulphostab" (Boots), a new intravenous organic arsenical; and "Acriflavine" (Boots) in neutral ½ gr. enteric-coated tablets.—[34] Burroughs Wellcome and Co. (Snow Hill Buildings, E.C. 1) had a beautifully arranged exhibit illustrated by illuminated coloured transparencies depicting micro-organisms, taken from photomicrographs, and the various organs of the body. Appropriate drug preparations were shown with each, including "Ephedrine" for hay-fever and asthma, "Avenyl," and "Alepol" (hydnocarpus preparations), for leprosy; Kepler malt extract with hæmoglobin; irradiated ergosterol; Wellcome Brand Dick and Schick test products and gonococcal vaccine and serum; Ergotoxine Ethanesulphonate; synthetic and natural thyroxine, and many others.—[12] G. W. Carnrick Co. (Brooks and Warburton, Ltd., 40–42, Lexington-street, W. 1) showed their well-known gland products, including Hormotone, and their free book on "Organotherapy in General Practice."—[16] The Crookes Laboratories (British Colloids, Ltd., 22, Chenies-street, W.C. 1) had made several additions to their range since the previous year, particularly a 50 per cent. cod-liver oil emulsion in which the taste is entirely covered, and which mixes with almost any quantity of water and remains mixed for four or five days; the vitamins A and D and the iodine content are independently standardised. Two forms of collosol lead were on view—a 0·5 per cent. and a 0·1 per cent.—[1] Messrs. Duncan, Flockhart and Co. (Edinburgh and London) gave special prominence to a display of anæsthetics, organo-therapeutical elixirs and tablets, and ophthalmic and nasal plastic gelatin capsules. The grasses and pollens used in preparing idiopathy tests were exhibited, and attention was drawn to hypodermic solutions, including pituitary, pituitary and adrenalin, peptone, asensitine, and the guaiacol-iodine-camphor compound for rheumatoid arthritis.—[15] Evans, Sons, Lescher and Webb, Ltd. (56, Hanover-street, Liverpool, and 50, Bartholomew-close, E.C. 1), showed a series of bacteriological products and drug preparations, including carefully standardised gland products; infundibulin (containing 10 clinical units per c.cm.); purgoids; sexatones (pluriglandular tablets); and the hydnocarpate and morrhuate of sodium, for leprosy and tuberculosis respectively.—[40] J. Gardner and Son (32, Forrest-road, Edinburgh) presented a large number of surgical instruments, many associated with the names of Scottish surgeons, a special exhibit of rustless and stainless steel, and the "Universal" operating table, with many original features.—[65] Genatosan, Ltd. (Loughborough, Leicestershire), showed, in addition to the familiar Sanatogen, Genasprin, Cystopurin, &c., a coryza spray and a series of local immunity antivirus vaccines for external application.—[21] The Hoffmann-La Roche Chemical Works, Ltd. (51, Bowes-road, N. 13), drew attention to their new laboratories, from which come many well-known preparations including "Omnopon," "Allonal," "Isacen," "Sedobrol," and "Somnifaine"—a liquid hypnotic for oral, intramuscular, or intravenous administration.—[8] J. F. Macfarlan and Co. (109, Abbeyhill, Edinburgh, and 32, Bethnal Green-road, E. 1) were the proud possessors of a letter from Lister about the application of cyanide gauze. They also showed a piece of the original carbolic gauze made for him, and catgut ligatures prepared from his and many other formulæ. Other exhibits included a series of fine pharmaceutical chemicals, notably salicin, pure and safe anæsthetics, and "Opoidine," a standardised preparation of the alkaloids of opium.—[36] Oppenheimer, Son and Co., Ltd. (179, Queen Victoria-street, E.C. 4), had a new form of vaporiser, which reduces all liquids, even non-volatile salts, to a fine, invisible smoke which is not condensible. The popular "Bipalatinoids" and "Pulverettes" were present in many varieties. A new preparation was "Maglactis," a magnesia suspension in gel condition, which never precipitates out. "Roboleine" and "Ung. Anæsthetic Renaglandin" for piles were also shown, and there was a new oxygen generator for producing 99 per cent. pure gas from chemical cubes in the same way as acetylene is made.—[38] Parke, Davis and Co. (50, Beak-street, W. 1) showed a range of eye ointments in collapsible tubes, and of gland preparations, notably parathyroid, guaranteed 90 per cent. pure. Among bacteriological products were the scarlet fever streptococcus antitoxin, preparations for the Dick and Schick test, and the public school anticatarrh vaccine. Sanocrysin was on sale this year, and Hæmoplastin had been improved by a reduction in its protein content. Also on show were "Hypotensive tablets" for blood pressure and "Agar crisp," a laxative resembling a breakfast-food.—[50] The Sandoz Chemical Works (5, Wigmore-street, W. 1) introduced a new calcium preparation, an oxidation product of glucose which can be used intramuscularly or intravenously. "Femergin" and "Lobeline" need no description.—[33] Schering, Ltd. (3, Lloyd's-avenue, E.C. 3), showed "Veramon—the safe analgesic"; Medinal; Neutralon, an antacid, astringent, and analgesic; cubes of pure camphor made from oil of turpentine; Müller's (Schering) conglobation test, and "Krysolgan," a gold preparation for tuberculosis and lupus erythematosus.—[18] E. H. Spicer and Co., Ltd. (72 Wigmore-street, W. 1), are the sole distributors in Great Britain for the Abbott Laboratories, Chicago, the Dermatological Research Laboratories, Philadelphia, and the Chemisch-Pharmazeutische A.G., Bad-Homburg. The chief among many exhibits was their *B. acidophilus* emulsion (Morbact) containing sufficient agar to

keep the bacilli alive and mineral oil to exclude air and protect them from the gastric juices.

2. *Special Drug Exhibits.*

[59] The Anglo-American Oil Co., Ltd. (Albert-street, N.W. 1), displayed their well-known "Nujol," "Cream of Nujol" (paraffin with agar), and "Mistol." The latter is now issued in an atomiser bottle.—[80] Behring Institute (Marburg-L., Germany, and W. Bredt, 41, Great Tower-street, E.C. 3) presented Yatren 105 for chronic amœbiasis and dysentery. Interest was aroused by the new Behring venule for sterile withdrawal of blood, a most convenient piece of apparatus.—[81] Bristol Myers Co. (112, Cheapside, E.C. 2) showed "Sal Hepatica," a saline regulator; "Ipana" tooth-paste; and "Ziratol," a hæmostatic antiseptic.—At Stand 19 Eno's Fruit Salt was dispensed and at Stand 99 Ichthyol Co., Ltd. (18, Adam-street, W.C. 2), showed the original ichthyol in 5 per cent., 10 per cent., and 20 per cent., preparations, and also "Ichtholan," a weak salve made up with equal parts of vaseline and lanolin.—[22] Kaylene, Ltd., showed their colloidal kaolin, also kaylene-ol, an emulsoid combination with colonol liquid paraffin (for which this firm are distributors). Colonol is also prepared with raspberry flavouring for children. Other combinations of kaylene-ol shown were with phenolphthalein (0·5 per cent.) and with magnesium sulphate. As agents for Majornas Angbageri, Goteborg, this firm also demonstrated the Swedish Health Bread Kakrispa, containing 100 per cent. whole-grain rye.—[103] Matthews Laboratories, Ltd. (Clifton, Bristol), in a bower of foxgloves and black cats, displayed the biologically standardised Hatcher cat-unit digitalis. "Nostroline" in the special nasal nozzle tube was also on view.—[14] The four varieties of Petrolagar were shown by the Deshell Laboratories, Ltd. (1/3, Brixton-road, S.W. 9). The plain is a 65 per cent. pure paraffin with agar; the others are unsweetened, alkaline (with magma magnesia), and phenolphthalein.—[69] Scott and Turner, Ltd. (Newcastle and 211, Blackfriars-road, S.E. 1), had an amusing model stage on which the preparation of a dose of Andrews Liver Salt was enacted.

3. *Miscellaneous Preparations.*

[24] Kolynos Incorporated (Chenies-street, W.C. 1) showed their dental cream in its familiar form and also in a concentrated liquid preparation for use as a mouthwash or gargle. Quite new is their "denture powder" for plates, and their skin soap.—[62] Jeyes Sanitary Compounds Co., Ltd. (99, Regent-street, W. 1), showed a comprehensive range of "Cyllin" toilet and surgical preparations, and drew especial attention to "Lano-cyllin," an antiseptic ointment, and "Branalcane," a 33 per cent. solution of glycyl borate in glycerine for diphtheria, sore-throats, &c.

FOODS.

[51] Benger's Food, Ltd. (Otter Works, Manchester), was represented, as well as the other products of the company, notably the peptonised beef and chicken jellies.—[31] Cadbury Bros., Ltd. (Bournville, near Birmingham), provided cocoa for the weary, and showed their range of chocolates, including the less familiar bitter, orange, and milk-and-honey varieties.—[88] Equally refreshing were the glasses of Gaymer's Cyder and Perry (Wm. Gaymer and Son, Ltd., Attleborough), which have been cooling the members of the B.M.A. annual meetings since 1898.—[17] Glaxo (56, Osnaburgh-street, N.W. 1) laid stress this year on Ostelin cream, a 50 per cent. emulsion to which ostelin has been added. Ostelin is also supplied in tablets, each being the equivalent of 1 drachm of cod-liver oil. Malto-Yerbine, the nutrient expectorant, is now available in a new liquid form.—[61] Granose Foods, Ltd. (Watford), showed "Granose" biscuits, made from 100 per cent. whole wheat; "Granovita" gluten bread and biscuits, and gluten meal.—[49] Horlick's Malted Milk Co., Ltd. (Slough, Bucks), had their well-known invalid diet in powder and tablet form.—[60] Keen, Robinson and Co., Ltd. (Carrow Works, Norwich), showed Almata, the synthetic milk food for infants, invalids, and nursing mothers. Robinson's groats, oats, and barley and Keen's mustard ointment were also displayed.—[11] Mead, Johnson and Co. (London Agents: Brooks and Warburton, Ltd., 40/42, Lexington-street, W. 1) showed "Recolac," their reconstructed milk food; "Casec," soluble calcium caseinate, and standardised Newfoundland cod-liver oil.—[73] At the stall of Montgomerie and Co., Ltd. (Ibrox, Glasgow), was found Berina food for infants, Berina malted milk food for older babies and invalids, and Bermaline bread.—[84] The Nestlé and Anglo-Swiss Condensed Milk Co. illustrated their exhibit with a series of photographic transparencies showing the process of manufacture. In addition to condensed milk attention was drawn to a sterilised cream and to the milk food on which seven generations of healthy rats have been reared.—[26] Oxo, Ltd. (Thames House, Queen's-street Place, E.C. 4), showed their meat juice, containing soluble uncoagulated proteins, and their "Oxoid" standardised endocrine preparations, as well as "Oxo," "Hospital Oxo," and "Lemco."—[58] Sister Laura's Infant and Invalid Food Co., Ltd. (Bishopbriggs, Glasgow), showed the baby and invalid food known by this name, and [30] Virol, Ltd. (Hanger-lane, Ealing, W. 5), laid particular stress on "Virol and Milk" for athletes, nursing mothers, and all cases of debility.—[116] Vitalia, Ltd. (17, Boniface-street, S.E. 1), showed the meat juice of this name, containing vitamins, organic salts, and 8 per cent. hæmoglobin without extractives.

SURGICAL INSTRUMENTS.

[42 and 53] Allen and Hanburys, Ltd. (48, Wigmore-street, W. 1), exhibited a wide range of surgical instruments and hospital furniture, some in German silver and cellulose enamel (for use abroad). Among the former may be mentioned the A. and H. patent knife handle, the first to be made with detachable blades in England; Souttar's craniotome and steam cautery apparatus, all-British cystoscopes, Lipiodol syringes, Rowland's fasciatome, Chevalier Jackson's endoscopic instruments; Magill's intratracheal spatula with battery in handle. The St. Bartholomew's Hospital pattern operation table had an adjustable clamp and new patent skull support.—[45] Arnold and Sons (John Bell and Croyden, Ltd., 50/52, Wigmore-street, W. 1) had a large series of surgical instruments on view, including a 1927 operation table on oil-pump base; a high-pressure steam vacuum steriliser, with improved radial-arm wheeled door; a new trolley for ward or theatre; goitre and mastoid instruments, as used by Mr. C. A. Joll and Mr. F. F. Muecke; Ironside's portable gas, oxygen, and ether apparatus; Phonophore stethoscopes; a special self-retaining retractor with adjustable blades; a universal battery for illuminating instruments needing 1½ to 8 volts; a syringe for regional anæsthesia; a new model of the Zund-Burguet electrophonöide apparatus; and a special combination pocket set of electrically lit examination instruments for eye, ear, nose, and throat.—[39 and 87] Down Bros., Ltd. (21 and 23, St. Thomas's-street, S.E. 1), showed a selection of surgical instruments and appliances, including many in stainless steel. Among the latter is a new instrument table. Putti's orthopædic table, gouges, and chisels; Howarth's bronchoscopy set; and Ivan Magill's new portable intratracheal apparatus merit special mention.—[112] The Genito-Urinary Mfg. Co., Ltd. (64, Great Portland-street, W. 1), had a series of surgical and optical instruments, with London-made lenses; boilable cystoscopes of several patterns, including Mr. J. Swift Joly's new model universal, with retrograde attachment for diathermy, and cysto-urethroscope for examination and operation in the bladder and posterior urethra; a large model diathermy machine with dry spark-gap; Chevalier Jackson's instruments; and a new electric steriliser for ureteral

catheters. As sole agents in Great Britain, this company had a show of drainage-tubes by J. Eynard, Paris.—[110] Holborn Surgical Instrument Co., Ltd. (26, Thavies Inn, E.C.1), displayed a selection of surgical instruments in stainless steel and electro-medical apparatus, including the latest models of diathermy electrodes, especially a new Stebbings pattern for prostate; Holme's and Beck's naso-pharyngoscopes; posterior urethral tubes for Harrison's aero-urethroscope; an illuminated corneal magnifier; and French's blood-aspiration apparatus and needle with cutting edge on back for easy introduction, tapering bore, and smooth lumen.—[27] Mayer and Phelps (Chiron House, 59/61, New Cavendish-street, W.1) showed many all-British instruments, including the Chiron chloroform inhaler, designed to eliminate all possibility of pumping out liquid chloroform; Dougal's bladder retractor for Cæsarean section; Guthrie's cheek retractor; Ede's tonsil-suturing forcep, which enables the knot to be tied outside the mouth; various gastro-intestinal instruments, notably Max-Page's pyloric forceps and Brown Kelly's modification of Gottstein's dilator for cardiospasm. A demonstration model of Rowling's anæsthetic outfit for supplying a warm atmosphere of oxygen, nitrous oxide, or carbon dioxide, or any combination of these, with or without chloroform, was working beside the stand.—[93] Smith, Hurford, and Drysdale (21, Lauriston-place, Edinburgh) showed surgical instruments and appliances, specially drawing attention to those by Edinburgh surgeons, including Prof. D. P. D. Wilkie, Mr. C. W. Cathcart (a low pressure steriliser), and Mr. Norman Dott.—[90 and 91] Ogilvy and Co. (20, Mortimer-street, W.1), as agents for Stille, of Stockholm, showed for them an inexpensive operating table with foot pump elevating gear, and high grade instruments, many in stainless steel.—[64] John Weiss and Son, Ltd. (287, Oxford-street, W.1), pointed out among their exhibit of instruments De Martel's intestinal clamp, Sinclair's instruments for intracapsular extraction of the lens, Canny Ryall's cysto-urethroscope with specially designed flexible shaft forceps and scissors, and a flexible, boilable lamp for rectal or bladder work.—[56] A. Young and Son (57, 59, 61, Forrest-road, Edinburgh) showed general and surgical instruments in large variety. The firm was associated with Simpson and Lister. Among hospital furniture was exhibited the Morrison bed frame, electric water-heaters and sterilisers, and a soiled dressing bin with pedal.—[9] Theodore Hamblin, Ltd. (15, Wigmore-street, W.1), exhibited a number of ophthalmic instruments, including a student's luminous ophthalmoscope convertible to non-luminous pattern, Lister hand projection lamp with transilluminator, Hertel exophthalmometer, and a new Worth amblyoscope with original pictures.

(To be concluded.)

DONATIONS AND BEQUESTS.—The Vice-Chancellor of the Chancery of Lancaster on July 25th approved payment of bequests under the will of Mr. William Fletcher Rogers, who left estate proved for probate at £76,214, and directed that the residue, £47,000, should be distributed among deserving charities in Cheshire at the discretion of his two sisters and his executors. Amongst the bequests are: £6300, Liverpool Open-air Hospital for Children, Leasowe; £5670, Victoria Central Hospital, Wallasey, and Wallasey Dispensary; £5558, Wallasey Cottage Hospital; £5670, Birkenhead and Wirral Children's Hospital; £2000, Birkenhead Borough Hospital; £1000, Chester Council of Social Welfare; £700 each, Nantwich and District Cottage Hospital, Crewe Memorial Cottage Hospital, Hoylake and West Kirby Queen Victoria Memorial Cottage Hospital and District Nursing Association, and the Heswall Branch of the Royal Liverpool Children's Hospital; £600 each, Wallasey Invalid Children's Hospital and Wallasey Police Distress Fund.—Mr. James Guthrie, Dundee and Broughty Ferry, merchant, on the death of his wife left, among other bequests, £2000 to the Dundee Royal Infirmary to endow a bed in memory of his parents, and £500 each to the Dundee Convalescent Home, the Sidlaw Sanatorium, the Dundee Sick Poor Nursing Society, and the Royal Victoria Hospital, Dundee (for the out-door relief fund).

Reviews and Notices of Books.

THE THOMAS SPLINT.

By MEURICE SINCLAIR, C.M.G., M.B., Ch.B. Edin., late Major, R.A.M.C.; Specialist in Fractures and Orthopædic Surgery to St. James's Hospital, London. With a Foreword by Sir ROBERT JONES, K.B.E., C.B., F.R.C.S. London: Humphrey Milford. 1927. Pp. 168. 15*s*.

THIS book is a real contribution to the surgery of fractures, and could only have been written by a surgeon with the unique experience of the author. Major Sinclair was quick to grasp the principles of application of this useful splint, which was invented by Hugh Owen Thomas, and the numerous possibilities of its adaptation to many needs. By painstaking work Major Sinclair has been able to standardise the use of the splint in a way which makes it a simple procedure to apply it to many varieties of fracture. So adaptable is the Thomas principle that this book might well be called a treatise on fractures of the long bones.

Many interesting statements are made. We read that direct bone extension is necessary in 15 per cent. of fractures of the femur, and that movement of the knee joint of 90 degrees and more is possible in the majority of cases after complete immobilisation for five or six weeks. In the description of the Thomas splint for the leg the lowest level of the ring is stated to be at the junction of the ring and inner upright. Surely the lowest point of the ring should be at the point where the tuber ischii comes in contact with the ring, so that naturally, with any displacement, this bony point of counter-extension will always tend to slip back and remain in contact with it. On page 57 the principle of Thomas is frankly abandoned in the early treatment of fractured femur because of the discomfort of the necessary pressure on the tuber ischii. The method recommended is no better than simple extension in a trough. The jettisoning of Thomas's method is quite unnecessary, as the pressure on the tuber ischii can be relieved to any extent (it should never be quite compensated for) by pulley extension from the lower end of the splint. Such traction is actually recommended for old people on page 58 without apparent realisation of the fact that careful graduation of the pull allows the Thomas principle to be preserved. We are glad to see the author insists that mechanical extension from the tibia is preferable to extension from the femoral condyles.

Fractures of the lower end of the humerus are always very difficult to treat. It is therefore with interest that we find Major Sinclair asserting that better results can be obtained by straight extension in a Thomas splint than by open operation. His fixed and movable elbow joint splints for fractures of the humerus are most ingenious and would seem to meet every requirement of these fractures. His modification of the Thomas arm splint, the umbrella splint, should be more often seen in use. It is an important addition to the appliances at our disposal. We congratulate the author on the production of a very practical and original guide to the management of fractures of the long bones. The methods described, complicated as they may appear from the illustrations, which are many and well drawn, are in reality quite simple.

DIE GASTROSKOPIE.

By Dr. ROGER KORBSCH. Chefarzt des Elisabeth-Krankenhauses, Oberhausen. Berlin: S. Karger. 1926. Pp. 76. M.4.20.

THIS is a short but valuable monograph describing the technique of gastroscopy as followed by the author, and the appearance of the stomach in health and disease. The author uses an instrument of his own pattern with a soft extremity, the passage of which he declares to be almost without danger.

He has performed, in fact, 300 gastroscopies without a single mishap. These examinations were carried out under local anæsthesia, but endoscopy of the stomach obviously requires considerable skill in the operator and coöperation on the part of the patient. Occasionally, more than one attempt has to be made before it can be carried out. Whether gastroscopy will become as simple a procedure as cystoscopy will depend upon future developments, but it would seem that Dr. Korbsch has done something towards making it a commonplace method.

In an interesting chapter on the genesis of penetrating ulcers of the stomach he gives reasons for believing callous gastric ulcers to arise from chronic gastritis. In this latter condition he has observed simple surface ulcers and all stages between these and ulcers accompanied by a demonstrable niche in the radiogram. He declares that the persistence of typical gastric ulcers depends upon the situation in which they arise rather than in any specificity of origin.

A MANUAL OF GENERAL MEDICAL PRACTICE.

By W. STANLEY SYKES, M.A., M.B., B.Ch. Camb., D.P.H. Lond. London: H. K. Lewis and Co., Ltd. 1927. Pp. xi.+216. 7*s.* 6*d.*

Dr. Stanley Sykes has provided the medical profession with a readable and competent book. It contains a variety of information of practical value, well arranged, and on the whole treated with due proportion—the author must have had much difficulty in deciding what to insert and what to omit in so small a volume with so large a reference. The hints as to the conduct of general practice, though very brief, are sound, while the chapters on the superstitions and idiosyncrasies of patients, and that on the occurrence of disease in general practice, should be really informing to the young practitioner. To treat of diagnosis, prognosis, and treatment in some 30 pages is to acknowledge that only teaching of the most cursory nature can be imparted, but the information has been shrewdly selected with an eye upon practical purposes, and is well supplemented by a section upon certain strange and unusual symptoms and happenings that may find reflection in any doctor's case-book. There are chapters on anæsthetics in general and on anæsthetics in practice, some reflections upon vaccination and vaccines, and on the incidence of venereal diseases, and a chapter on midwifery which is prefaced rightly by a note that criticism of the midwifery of the general practitioner appears always to come from those who have not been in general practice.

This is an interesting and useful little manual written from the general practitioner's point of view, and laying stress on what the author calls "non-hospital diseases." It should find many readers.

THE ANATOMICAL BASIS OF DISEASE.

Anatomische Grundlagen wichtiger Krankheiten. Second edition. By Dr. LEONHARD JORES. Berlin: Julius Springer. 1926. Pp. 525. M.48.

THE second edition is almost double the size of the previous one, and, owing to the addition of new subject matter and the altered arrangement, the book is practically a new one. The aim of the author, in which he succeeds admirably, is to correlate pathological anatomy with clinical findings, and to give the physician a picture of the physical structure underlying disease. After a short but instructive introduction on cellular pathology and local and general infection, he considers disease under the following headings: metabolic disturbances, derangements of internal secretion, localised circulatory disturbances, inflammatory and infectious diseases, diseases due to animal parasites, post-infective conditions and toxic changes, regeneration, wound healing and tissue reaction to foreign bodies, tumours, and anatomical defects. An appendix deals with the chondrodystrophies and ectopic gestation. The book contains an immense amount of interesting information which the author has had difficulty in arranging. For example, the section on infective conditions and toxic changes deals, amongst other things, with endocarditis, encephalitis, syringomyelia, acute nephritis, anæmia, metallic poisoning, phosphorus and salvarsan poisoning, ergotism and botulism.

The book is profusely illustrated with excellent photographs of pathological specimens and coloured drawings, and can be recommended to pathologist and clinician.

PSYCHO-PATHOLOGY OF TUBERCULOSIS.

By D. G. MACLEOD MUNRO, M.D., C.M., M.R.C.P. Edin. London: Humphrey Milford, Oxford University Press. 1926. Pp. 92. 5*s.*

IN the preface of this book Dr. D. G. MacLeod Munro frankly and courageously commits himself to the view that there is a definite psychical state which may be fairly referred to as characteristic of tuberculosis. The novelists have made much of this state, but the sober pages of medical literature are by no means so clear, as Dr. Munro's bibliography shows. Any toxin circulating in the body is liable to produce changes in a patient's temperament. This is a commonplace of clinical medicine. But to attempt to correlate these changes with any theory of psychology, or to identify them with the toxin of tuberculosis in particular, is woefully hard. Indeed, Dr. Munro's book seems to demonstrate that it cannot be done with our present knowledge. The facts are all too vague, and the author himself has not really succeeded in producing a clear picture of the psycho-pathology of tuberculosis. Medical opinion does not appear to be any more definite on the question of phthisis and insanity. The view is expressed in this book that there is some ætiological association between tuberculosis and insanity from the point of view of inheritance. Here, again, the author has to fall back on vague clinical impressions. The book also contains three chapters on tuberculosis and genius, and a concluding chapter by Dr. Leonard Browne on psychotherapy in tuberculosis. The first two of these chapters are brief descriptions of the lives and works of certain well-known writers who are known to have suffered from pulmonary tuberculosis; the last one gives practical advice as to the treatment of insomnia, the phobias, mental instability, and so forth, in phthisis by various psycho-therapeutic measures. The book is an honest attempt to deal with an elusive subject, in which there is really not yet available sufficient classified material to provide a definite message.

BIRTH CONTROL.

By JOHANN FERCH. Translated by CHRISTIAN ROLAND. With an introduction by MAUD ROYDEN. London: Williams and Norgate, Ltd. 1927. Pp. 124. 3*s.* 6*d.*

THIS book is written by the foremost Austrian protagonist of birth control. Though the method of election of Herr Ferch is such as might provoke criticism on medical grounds, the claim is made that it is being practised with complete success in the 50 districts into which Vienna has been divided by the League for the Protection of Motherhood, of which the author of this book is the president. The method consists in the fitting upon the cervix of an occlusive cap made of silver or other incorrodible metal by a doctor every month. When her menstrual period is over, the woman visits one of the centres of the League, her cervix is ascertained to be healthy and the metal cap is adjusted. This is left in situ until the beginning of the next menstrual period when it is removed by the woman, and left off till the end of the period, when it is again fitted by a doctor. It will be seen that this method requires that the woman shall make a visit every month to a birth control centre. It is claimed of this technique that lacerations of the cervix are never caused by a properly fitted pessary, and that the risk of pathological discharges being retained is small, since the

cap is lifted off the cervix by the pressure of the secreted matter. If the cervix is of a shape which does not admit of such a pessary being fitted, a "Dutch" pessary, made of rubber, is recommended. The rubber cervical cap is not mentioned. Vaginal douching after coitus is also advocated, but soluble pessaries are held to be of little value.

To this book an introduction has been written by Miss Maud Royden, and a biographical note upon Herr Ferch by Christian Roland, the translator. These writers dissociate themselves from a plea, made by the author, that abortion during the first three months of gestation should be sanctioned by law. Mr. Roland considers that such legislation would be in the highest degree inapplicable to this country, though he explains that during the famine years in Austria, when all children born were destined to get rickets, and when each birth diminished the average quantity of food per person, it might well be regarded as preferable to induce an abortion than to bring a living child into the world. A further argument in favour of this legislation in Vienna is the prevalence of quack abortionists, who are apparently permitted to obtrude themselves before the public notice more than in other countries. Dr. Ferch holds that the present legal position with regard to abortion results in numerous people among the poorer classes in Austria resorting to these quacks, to the great detriment of their health.

DIAGNOSIS AND THERAPEUTICS OF DISEASES OF THE STOMACH.

Diagnostik und Therapie der Magenkrankheiten. Eighth and ninth edition. By Prof. Dr. I. BOAS. Leipzig: Georg Thieme. Pp. 817. M.42.

THE eighth-ninth edition of this classic has been greatly revised and brought up to date. The author has added a chapter on occult blood, while there is a considerable amount of new material supplied on the use and value of X rays. Peptic ulcers, both of the stomach and jejunum, have been extensively considered, while the sections on malignant tumours, benign tumours, and syphilis of the stomach have been subjected to searching revision. In this work Prof. Boas considers in detail all the various diseases of the stomach, and his opinions may be regarded as authoritative. The contents are divided into two main parts. The first deals with general examination, both physical and chemical, and contains a section on general treatment and considerations of diet. In the second part the various diseases are considered separately in detail, the sections on symptomatology and treatment deserving special praise. The section on dietetics is written with great minuteness, coloured tables showing graphically the fat, carbohydrate, and protein content of numerous foods and beverages.

The book is well illustrated, and there is a complete index both to subjects and to authors. References to the literature are given at the bottom of each page. Such a complete and exhaustive monograph on the diseases of the stomach cannot fail to be of value to physician, surgeon, and pathologist—the lessons might well be conveyed through them to the public in intelligible form, at a time when the diet of the people is under turbid and turgid discussion.

NURSING MENTAL AND NERVOUS DISEASES.

By ALBERT COULSON BUCKLEY, M.D., Medical Superintendent, Friends' Hospital, Frankford, &c., U.S.A. London: J. B. Lippincott Company. 1927. Pp. 312. 12*s.* 6*d.*

THIS latest addition to Lippincott's series of nursing manuals has been written to comply with the revised standard curriculum for American training schools (1926), and in it Dr. Buckley has given a comprehensive survey of the subject. The author specially stresses two points: (1) the need for treating each separate patient as an individual, and (2) the physical basis of all mental illness. These ideas are developed throughout the book, which is divided into four parts and is exceedingly well illustrated. The first part is concerned with a biological introduction and a clear and concise description of the central nervous system; the diagrams in this section are worthy of special mention. The other theoretical portions of the book are not so well defined, and are more difficult to follow; the student may well become confused by the introduction of somewhat discursive psychology. The second half of the work is devoted to a brief survey of the individual psychoses and the diseases of the nervous system; the nursing care required in each particular group is indicated. There is included a chapter on special nursing procedures, but the space devoted to actual nursing seems strangely inadequate for a work of this kind.

The general effect is that of a text-book of psychiatry which has been cut down, with brief hints on nursing interpolated, rather than that of a book primarily written for the nursing profession. The frequent use of block lettering for emphasis is disconcerting.

JOURNALS.

BRITISH JOURNAL OF OPHTHALMOLOGY.—April, 1927: The bulk of this number is occupied by a minute criticism of Barraquer's operation for the intracapsular extraction of cataract, by J. Russell Smith, the son of Lieut.-Colonel H. Smith, whose intracapsular operation is also well known. There is no doubt that in the hands of their inventors both these operations have proved remarkably successful. The Barraquer operation, however, has been tried on a large scale in India with results that can certainly not be considered encouraging. No doubt everything depends in this operation on the technique of the surgeon and upon whether or not the complicated instrument employed is in perfect order.—The number also contains a note by R. R. James on a case of "Krukenberg's Spindle," a rare corneal condition of uncertain causation, generally bilateral but in this case unilateral. The drawing appended will be useful for reference.——May, 1927: Parenchymatous Keratitis in Trypanosomiasis in Cattle and in Dogs, and in Man, by H. Neame. The evidence shows that this infection bears the closest resemblance clinically and pathologically to distemper keratitis in dogs and to syphilitic interstitial keratitis in man. —There are two papers on cases of atypical sympathetic ophthalmitis. D. J. Wood, of Cape Town, records a case in a fair-haired girl of 9, who contracted gonorrhœal conjunctivitis from a girl with whom she was playing. The cornea perforated with prolapse of iris, and in stitching a conjunctival flap over the hole the lens capsule was wounded, and most of the lens escaped. Rather more than two weeks later there were fine keratic precipitates in the other eye, and other signs of sympathetic, only discoverable with the slit-lamp. The exciting eye was promptly excised and energetic treatment applied. This consisted of (1) weekly injections of salvarsan; (2) six injections of autoserum; (3) atropine and dionine locally. In spite of the fact that definite signs of sympathetic were present in the sympathising eye before the excision of the exciting eye, the ultimate result was good, normal vision being restored. The other case is reported by T. Harrison Butler and J. Jameson Evans. It was not a true case of sympathetic ophthalmia, but a case of sympathetic inflammation, associated with intraocular sarcoma. A severe iridocyclitis in both eyes was due to toxins liberated by the necrosing action of the sarcoma. After excision of the exciting eye there was a rapid improvement in the sympathising one which eventually regained a vision of 6/12.—D. J. Wood: Calcium Deficiency in the Blood with Reference to Spring Catarrh and Malignant Myopia. This paper throws new light on both these diseases. Spring catarrh is explained as a reaction to climatic conditions—dryness, heat, and dust—in young children who have too little calcium in their blood. Small doses of parathyroid gland are found to increase the calcium-content to normal and by

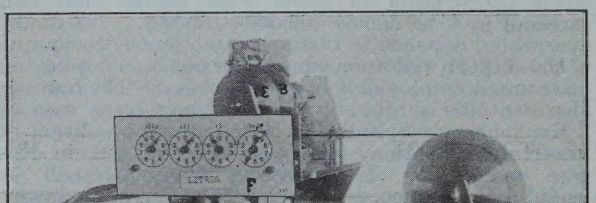
this means a cure is effected. The author suggests that a calcium deficiency in the blood may have some connexion on the one hand with a weakening of the cornea and development of conical cornea, and on the other with weakening of the sclera and development of malignant myopia. If this suggestion can be confirmed the matter is one of great importance, but the evidence so far produced is not very convincing.

New Inventions.

AN INTEGRATING DEVICE FOR CLOSED-CIRCUIT RESPIRATION APPARATUS.

WHEN performing experiments with respiration devices of the closed-circuit type, such as the Benedict metabolism apparatus or the U.S. Air Service "rebreather," it is sometimes desirable to know the total pulmonary ventilation as well as the amount of oxygen consumed by the subject during the period of the test. The amount of oxygen consumed is, of course, equal to the decrease in volume of the gas in the apparatus, and is read off directly from the scale on the instrument. The total ventilation may without appreciable error, be considered as the tota

FIG. 1.

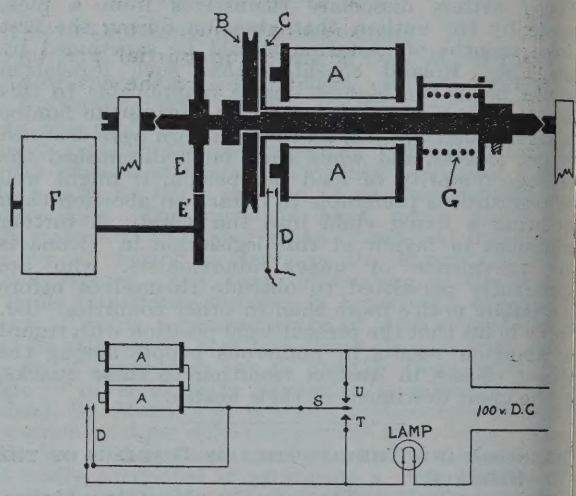


volume of all the inspirations, and may be calculated by mechanically integrating all the down-strokes of the spirometer bell. The simplest device for accomplishing this result is a ratchet wheel (Ludwig's work-adder) attached to the pulley over which the spirometer cord passes, but ratchets have the disadvantage of being both inaccurate and noisy.

The integrating apparatus here described was designed for use with the standard Benedict closed-circuit metabolism apparatus. It is attached to the top of the spirometer frame in place of the usual pulley-arm and pulley (Fig. 1). The down-strokes of the spirometer bell (inspirations) are integrated by means of a gear-train (E and E′) actuated through the agency of a magnetic clutch (C) mounted on the pulley-shaft (Fig. 2). The clutch is controlled by a tambour contactor (W) attached to the mouth-piece (P) of the metabolism apparatus (Fig. 3). During inspiration the clutch (C) engages with the pulley (B) and motion is transmitted through the gear-train (E and E′) to the dials (F). At the beginning of expiration the clutch is withdrawn and the pulley turns freely on the shaft during the expiratory phase. The total ventilation during the period of the test is read in litres directly from the dials.

In detail, the operation of the mechanism is as follows: As expiration begins a wave of air-pressure passes from the mouthpiece (P) along the tube (R) toward the spirometer (Fig 3). Part of its energy is transmitted to the membrane of the tambour (W which rises and causes a momentary electrica connexion between the contacts (S) and (T). Thi energises the magnets (AA) (Fig. 2) and the iro clutch (C) is withdrawn. In this movement the bac of the clutch-plate compresses the auxiliary contact (D), which are connected in parallel with (S) and (T and a steady flow of current is maintained throug

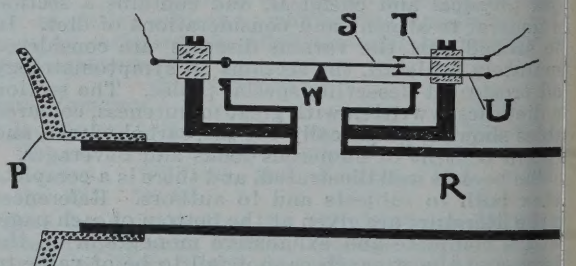
FIG. 2.



the magnets, regardless of any possible vibratio of the tambour contacts. Thus, during expiratio the clutch is held firmly against the pole-faces the magnets, the shaft, gears, and dial-pointers a at rest, and the pulley turns freely on the shaft.

At the beginning of inspiration the wave of negativ pressure draws the tambour membrane downwar making contact between (S) and (U). This shor circuits the magnets and releases the clutch, whic being pressed forward by the spring (G), instantl engages with the pulley. In this movement th pressure on the auxiliary contacts (D) is release and the circuit is broken. The pulley, clutch, an

FIG. 3.



shaft now turn together as the spir meter bell descends, and the motion transmitted through the gear-train (E a E′) to the dials.

Inasmuch as the magnet coils are short-circuite at the beginning of each respiration, batteries a not used. Current is supplied from the 100-vo direct current mains, and its flow limited by th inclusion of a 50-watt lamp in the circuit. Sin it requires an appreciable length of time for th wave of air-pressure to traverse the length of th tube connecting mouthpiece and spirometer, th quick-acting clutch mechanism will have complete its operation before the spirometer begins to mov Hence there is no error due to lag in the apparatus.

The instrument was built by Mr. S. W. Bus Oxford Scientific Instrument Works, Wheatsheaf-yar Oxford.

THE LANCET.

LONDON: SATURDAY, AUGUST 13, 1927.

HE TRANSFER OF PRACTICES: A LOAN SCHEME.

In the section dealing with the transfer of practices, ntributed to "The Conduct of Medical Practice" y Mr. O. A. HEMPSON and Mr. C. M. OLIVER, licitors to the Medical Defence Union, it is pointed ut that the majority of medical men have at some me or other in their professional career to consider e purchase of a practice or of a share in one; and e writers show that in this vital matter an initial istake may have disastrous results for an unwary rchaser. They proceed to classify the points which ve to be remembered by the purchaser and by the ndor, as they bear on the class of practice which is be transferred; they discuss the merits of part rchase and the methods of payment. Whatever the pe of the practice may be, and whatever proportion its receipts is being made the subject of transfer, e purchaser will require full information before he in a position to judge whether any practice is ely to satisfy his requirements, while the vendor can ly be placed in a substantial position for the sposal of his interests if he has so conducted his siness affairs that he can prove the justice of the ice which he demands. In reaching any fitting rangement these are the essential preliminaries—so vious that only their more than occasional neglect stifies their mention.

But it frequently happens that, the ground having en cleared in a satisfactory manner, and the rchase price having been arrived at upon the proved sis of average gross receipts, the purchaser is unable find immediately the capital sum necessary to nplete the transaction. This is a familiar situation, d it follows that payments upon some agreed plan instalment are frequent. Contracts to this effect n be made readily where only a partial transfer of practice is in contemplation and where the future rk of the practice will be carried on through rtnership, but in these circumstances also a part yment of the full price is generally required. methods of payment by instalment, like all nplete purchases, must be founded upon a thorough estigation of the receipts and close scrutiny of the spects, and be made the subject of a properly wn legal instrument. In the majority of cases the ct of this will be that certain amounts of money be due by specified dates in accordance with any ion given to the purchaser, and to meet these ms adequate security will have to be found; so t whether the whole purchase price or some balance t, in bulk or detail, be required, the purchaser may urgent need for what the circulating usurer calls mporary accommodation." It has before now pened that money has been obtained upon rtunate terms to meet the situation, with the lt that the in-comer to the practice starts loaded n an uneconomical debt. It is true that this is n avoided, because the purchaser and the vendor equally familiar with the fact that substantial tal sums are often not forthcoming in bulk tly when the contemplated partnership might ruitful in results, so that arrangement through the medium of experienced medical agents can usually be effected. But some simple and recognised method for the provision of properly secured loans would be a valuable departure and of great convenience to many practitioners, not necessarily, moreover, those commencing practice.

At a meeting of the Committee of Management of the Medical Insurance Agency last March a scheme whereby practitioners may obtain financial assistance for the purchase of partnerships or practices was presented, and if worked out carefully it ought to solve many problems, which are sometimes urgent as well as delicate. The general principles of the scheme are quite simple. A proportion of the capital required for the purchase of partnerships or practices is to be provided by means of a loan, the arrangements for which will take place between the Agency and the doctor concerned. Full details of the practice will have to be supplied to the Agency, even though this ground may already have been covered to their common satisfaction by the contracting parties, for it is clear that these parties might, as between themselves, overvalue the property and thus seek a loan upon improper security. When the Agency is satisfied that a loan can be officially approved in respect of the sum it is proposed to borrow, which is one warranted by the receipts, and when the Agency is informed what sum the purchaser can find from his own resources, a life insurance policy will be taken out as collateral security for a loan. Only borrowers who are physically fit for life assurance can be helped on the most advantageous terms, and it is proposed to take out the life insurance policy for one and one-half times the amount of the loan, while at the same time a sickness policy is to provide the amount of weekly benefit equalling the total of the obligations created by the loan if the borrower is laid by and unable to continue earning. Thereafter the payment of interest and the gradual repayment of principal can be provided for by equal quarterly instalments spread over the period of four to ten years for which the loan is granted. It will be seen that there is nothing in this scheme which departs from the process, more ordinary in the age of private banking than it is now, of borrowing upon a sound business prospect with the collateral security of a life-policy. The Medical Insurance Agency is filling the useful rôle of guarantor. Having satisfied itself that the professional prospect is sound, the Agency proceeds to back its opinion by a short-term loan, protecting itself by outside assurance against its client's illness or death. The client is trebly advantaged: first by an expert opinion that he is buying a sound thing, secondly by a loan on reasonable terms (the interest charged is about 8 per cent.), and thirdly by the obligation to make wise provision against accident, illness or premature death.

THE DANGEROUS DRUG TRAFFIC.

THE efforts made by international coöperation to control the traffic in drugs of addiction and to limit production to medical and legitimate requirements have not hitherto been rewarded by very satisfactory results. The convention drawn up at Geneva in February, 1925, after two rather acrimonious conferences, has not yet come into operation. By its own provisions it cannot be put into force until it has been ratified by ten of its Signatory Powers, including seven of the principal States represented on the Council of the League of Nations, two of which must be States having permanent representation thereon. According to recent replies in the House of Commons, the only

States besides Great Britain which have at present deposited ratifications are the Netherlands, Czechoslovakia, Bulgaria, Poland, Portugal, the Sudan, and San Salvador. The sanguine anticipations of the President of the second and more important of the Geneva Conferences of 1924–25, that the new convention would "greatly strengthen The Hague Convention of 1912," and "accelerate from day to day and from month to month" the international control of the traffic in dangerous drugs, have not as yet been realised. An astute critic of the Geneva Conferences, Mr. J. P. GAVIT [1] would appear, thus far, to have been justified in his surmise that "the agreement of the first Conference represents no progress worth discussing, and the new drug convention adopted by the second is a thing of printed paper with the odds heavily against its ever being anything else."

Meanwhile, the Home Office has wisely thought fit to issue to the Press a report on the work that is being accomplished under the provisions of the International Opium Convention drawn up at The Hague in 1912, and these have been ratified by nearly every sovereign State in the world whether a member of the League of Nations or not. The report is one of a series made annually by the British Government to the League of Nations; it deals with work carried out in the year 1926, and is the first of the series to be published. Under the Dangerous Drugs Act of 1920, and subsequent amending Acts, which gave effect to the provisions of The Hague Convention from the national standpoint, the internal control of the manufacture, sale, distribution, import and export of opium, morphia, heroin, cocaine, and other substances is well in hand, and if other countries which are parties to The Hague Convention were to follow the example of Great Britain in regard to legislation and administration great progress might be achieved. Thus it is gratifying to learn that the exports of British-manufactured morphia, which amounted to 14 tons in 1914, have been reduced to 73,289 oz. in 1926—a diminution of more than five-sixths. It appears that seven firms are licensed to manufacture medicinal opium, but the preparation of morphine is restricted to two firms, both situated in Edinburgh. Indian opium, which was formerly regarded as too poor in its morphia content, was in 1926 imported into Great Britain in larger amount (95,173 lb.) than was Turkish opium (40,885 lb.). Some Indian opium (3040 lb.) was re-exported to the United States. Steps have been taken to ascertain the consumption of opium, morphia, heroin, and cocaine in hospitals in Great Britain in 1925 The estimated amounts were as follows: Opium, 750 lb.; morphia, 1149 oz.; heroin, 403 oz.; cocaine, 1669 oz. When attention is directed to the international aspect of the traffic in these dangerous drugs it is not reassuring to learn that "information received by His Majesty's Government during the year shows the illicit traffic in drugs continues on a large scale." Seizures in some cases of thousands of ounces of the smuggled alkaloids have been made. The tricks of illicit traffickers are manifold and ingenious. Walking-sticks, pianos, bedsteads, chairs, concealed belts, confectionery have been variously employed to elude customs officers and preventive men. False labels and unauthorised import certificates have been resorted to. Powerful syndicates are believed to conduct the operations of this contraband trade in the Far East, consisting, as was stated at Geneva, of "coteries of people willing to poison their fellows for profit."

All available evidence serves to confirm the view that the world production of these dangerous drugs is greatly in excess of the world's legitimate need, and that the surplus production is easily diverted into illicit and pernicious uses. Both the Council and the Assembly of the League of Nations have recorded the general desire to reduce and restrict production to medical and legitimate purposes, while a joint subcommittee of its Health and Opium Committees proclaimed that "the medical use should be considered the only legitimate use, and that all non-medical use should be regarded as an abuse." The correlation of production and legitimate use of these drugs is necessarily and essentially a problem demanding vigilant international coöperation. The question is to be discussed at the meeting of the Inter-Parliamentary Union to be held in Paris next month. It behoves the representatives of the many legislatures which will there assemble to move their respective Governments to more active effectuation of the international obligations by which they have already bound themselves.

INTESTINAL OBSTRUCTION.

DEATH from intestinal obstruction presents certain peculiar features. Its onset is inevitable, but its arrival is often unexpected. Suddenly and without warning the patient's condition gets worse, and he succumbs within a few hours; so rapidly does he go downhill that any attempt to save him by surgical operation is a forlorn hope. Very much work has been done to elucidate the pathology of intestinal obstruction but its mechanism still remains obscure. Mr. ST. LEGER BROCKMAN in his Arris and Gale Lecture, published elsewhere in this issue, brings forward some experiments from which he infers that the prevention of the passage of bile along the alimentary canal is one of the main causes of the symptoms which characterise the condition. After confirming G. H. WHIPPLE'S experiments, which show how fatal it is to leave a closed duodenal loop although continuity of the alimentary canal is maintained by a gastro-jejunostomy, he went further and found that if, instead of a gastro-jejunostomy, a lateral anastomosis is made between the duodenum just above the loop and the jejunum below, the animals survive much longer and do not show the rapid and severe symptoms associated with the Whipple experiment.

To test his simple explanation of these phenomena Mr. BROCKMAN tried administration of bile, by the rectal route, to patients with intestinal obstruction. Thirteen patients were treated in this way and one four died; in those who recovered the vomiting toxæmic symptoms, and lethargy were banished. The dose given was 2 oz. of bile in 4 oz. saline every four hours. Relief was almost immediate and when in several instances administration of bile was stopped, the symptoms returned, only to be dispelled again by resumption of the bile enemata. Human bile seemed to be much more effective than ox-bile, which gave rise to abdominal pain necessitating the use of morphia. The clinical histories of the three successful cases reported will be submitted to minute and critical examination. The first was that of a man who had had a gangrenous appendix removed some days previously. His symptoms disappeared under treatment, but the account leaves the reader in doubt as to whether he was suffering from obstruction of the intestine or from acute dilatation of the stomach, and it is uncertain whether his recovery was due to natural disappearance of the obstruction to the stomach or ileum or may be attributed to the

eatment. The second case followed such an unusual urse that it is difficult to attribute the result to ything except the treatment employed. The mptoms came on after an operation for appendicitis, d on the fourth day the patient had stercoral miting and hiccup. There was no result from an ema. Administration of bile relieved the symptoms d kept them in abeyance until the tenth day. that day he had no vomiting, and only slight dominal distension; his pulse-rate was 70; felt well, read the paper and smoked; yet a arotomy showed "an absolute obstruction by an ental band about six inches from the ileo-cæcal lve." In the third case, again, the condition may ite well have been acute dilatation of the stomach obstruction due to adhesions, which as every surgeon ows, often recover spontaneously with the subsidence the pathological process in the right iliac fossa. ry remarkable, however, is one of the failures. woman of 65 was operated upon for strangulated nia, but the surgeon did not relieve the obstruction he did not detect a strangulated loop "in the other f of the bilocular hernial sac." With complete chanical ileus this patient was for 16 days kept e and remarkably fit by means of bile injections. Undoubtedly the procedure merits further inquiry l trial, but it is to be hoped that investigators will alive to the fact that (as Mr. BROCKMAN shows) symms of true mechanical obstruction may be masked such an extent that operative relief is delayed il it is incapable of saving the patient's life.

Annotations.

"Ne quid nimis."

SLEEP.

ONE of the sessions of a recent neurological congress Paris was devoted to the subject of sleep in its mal and pathological aspects.[1] Since the fundaital work of Piéron in 1912, knowledge of sleep advanced mainly in two ways: Pavlov's experiital researches have led to the conception of an bitory mechanism, and clinical observations, ecially on cases of lethargic encephalitis, have ght new evidence in favour of the existence of a lating centre. The openers of the discussion—A. Tournay and Prof. J. Lhermitte—had evidently much influenced by these newer contributions he subject. Dr. Tournay, in dealing with the siological side, first referred to the state of the cular and sensory systems and of the vegetative tions during sleep, and then discussed the acteristics and variations of sleep, its immediate ses, and the nervous mechanism by which it is ced. The somatic musculature, he said, seems e more or less relaxed, but its relaxation is not orm or constant. In children sleeping with their closed a degree of contraction of the flexors of fingers has been observed. It must be noted that the masticatory muscles are in a state of s and that the sphincters preserve their function; raction of the orbicularis oculi helps to keep the closed; the eyeballs are turned upwards and vards by muscular contraction and the activity he circular fibres of the pupil causes myosis. lon reflexes are in general diminished. Babinski's and the defence reflexes are present. Sensation general diminished, the threshold of excitability g greatly increased; hearing is the sense least ted. Breathing is slower and deeper, inspiration g longer and deeper, and expiration relatively ker than in the waking state, and ventilation is eased. The heart's action is slower by reason of a longer diastole and the blood pressure is slightly reduced.

The outward appearances of sleep do not warrant more than a presumption that the patient is sleeping. How can it be told that a man is really asleep? Piéron defined the sleeping state as "the absence of spontaneous dynamic activity and of voluntary reactions adapted both to the nature of the excitants and also to the diverse circumstances of place and time." To this Dr. Tournay adds the occurrence of the phenomena already mentioned and their reversal by the application of a moderate stimulus. This condition of being relatively easily aroused and restored to the waking state distinguishes the sleeper from the man who is in a coma or toxic stuporose state. The depth of sleep has been studied by means of graduated auditory stimuli. In most subjects sleep attains its maximum depth about the end of the first hour and thereafter the depth decreases more or less regularly till the moment of waking. But there are some people in whom the pattern is of an inverted type. The sensory side of thought preserves its activity during the time of falling asleep, but the motor or verbal side comes under the influence of sleep much more quickly. The persistence and perversion of sensory impressions produces "images hypnagogiques" which occur during the time of falling asleep and are not the same as dreams.

The immediate cause of sleep seems to be an inhibition of cortical processes; according to Pavlov, "internal inhibition of conditioned reflexes and sleep are one and the same process." Sleep as a pathological condition is to be distinguished from coma and the stupor produced by certain intoxications; real sleep as a symptom of a diseased state is seen chiefly in two conditions, narcolepsy and encephalitis lethargica. Narcolepsy (sudden onset of sleep so that the patient, if standing, falls down) is a symptom which may arise without known cause or may follow encephalitis or trauma, and there is considerable evidence that it occurs as a result of damage to the grey matter in the floor of the third ventricle, especially in its anterior (hypothalamic) portion. The study of encephalitis lethargica suggests that prolonged sleep may be brought about by inflammation affecting some structure in the anterior part of the mid-brain, and it may be that in this region there is convergence of paths leading to and from higher sleep-controlling centres.

ARTIFICIAL ŒSOPHAGUS.

THE condition of an otherwise healthy person condemned to a fistula life on account of an occluded gullet is a pitiable one. Since César Roux, of Lausanne, inaugurated the attempt 20 years ago, there have been a score of cases in which a successful attempt has been made to replace the stenosed œsophagus by an artificial tube extending from pharynx to stomach in the thoracic integument. Dr. A. Fonio reports,[1] from the hospital of Langnau, near Berne, the result after eight years of such an œsophageal plastic operation which has enabled the patient to sit at table and eat like an ordinary person. The history of the case dates back to the year 1908 when after a domestic quarrel the woman swallowed some crystalline permanganate of potash and developed a stricture near the cardia which gradually became impermeable so that for ten years she was dependent on fluid introduced through a gastric fistula. In 1919 Dr. Fonio, in a series of operative measures extending over 17 months, succeeded in improvising a functional œsophagus. In the first stage a piece of thoracic integument 22 × 8 cm. was converted into a skin-lined tube. In the second a piece of transverse colon 15 cm. in length was isolated, with retention of its arterial supply—colon being chosen in order to avoid the danger of gangrene experienced when a loop of jejunum is used for the purpose—to intervene between the stomach and the lower end of the skin tube. If we understand Dr. Fonio aright, it is important to

[1] Presse Médicale, July 13th.

[1] Schweizerische medizinische Wochenschrift, July 30th, 1927.

retain the peristaltic action of this colon tube in the downward direction. Finally, the upper end of the skin tube was sutured to the cut œsophagus through an incision in the neck, the thyrohyoid muscles being sewn into the upper edge of the incision in order to open widely the mouth of the skin tube at the moment of swallowing. Some minor difficulties and accidents were overcome to such effect that in 1921 food after mastication was delivered with lightning rapidity down the air-filled tube directly into the stomach via the section of colon. No retraction or retention occurred at any time in the lower or middle sections of the tube. Between 1921 and 1927, however, the development of a calcareous goitre resulted in gradual closure of the upper end of the skin tube and the necessity of reverting to the gastric fistula; after removal of the goitre patency was restored and the patient returned well nourished to her factory work. The only respect in which she does not now possess normal function is that she cannot vomit. The net result is a striking achievement in plastic surgery although the indications for its employment may not be frequent. It is obviously only applicable in non-malignant stricture, and Roux, who first devised the technique, gave it up later in favour of early and patient stretching of the stricture by the passage of metallic sounds. Biologically the operation is of interest, as it affords an example in later life of the method so familiar in embryonic development of the production of tubular structures by the tucking in of superficial layers of cells.

PROSPEROUS MEDICAL SCHOOLS IN AMERICA.

NEW endowments and gifts have recently made possible the extension and improvement of research and teaching in various American medical schools. The campaign of the "half century committee" of Johns Hopkins University resulted in a total of seven million dollars from 3992 subscriptions, and the General Education Board of the Rockefeller Foundation have given ¾ million dollars for a medical library at the same University. The new library will assemble 50,000 volumes from various departmental libraries, some of which are now a mile or two apart. The building is to be in the Italian Renaissance style, three stories high, and will house 400,000 volumes. It will be dedicated to Dr. William H. Welch, the first dean of the medical school and now director of the School of Hygiene and Public Health. The medical school of the University of Pennsylvania is raising a fund of three million dollars, of which nearly one-half has already been subscribed. This school has just announced the organisation of a new department of pathology which is to be under the direction of Dr. Eugene L. Opie. The medical schools at Albany and Detroit have each completed new six-story buildings which will replace their former domiciles. The teaching hospital at Detroit, now called the Detroit General Hospital, recently opened a million dollar extension. A million dollars has been received for the foundation of a new radiological institute for the Washington School of Medicine. The institute, besides providing facilities for research, will offer treatment with radium and X rays. In New York city a neurological institute is projected which will cost a million and a half, of which more than half has already been pledged. Western Reserve is raising six millions for a medical centre and is already starting to build a new pathological institute. Of these large sums of money a part is provided by the wealthy foundations peculiar to America, but a considerable proportion comes from the alumni of the Colleges themselves. How this is made possible is revealed by a questionaire recently sent out from the University of Oklahoma School of Medicine to 304 of its graduates. Of the majority who replied the monthly income is said to range from $300 to $4000, with an average of $1100. Most of these graduates are practising medicine in their home State. The State medical journal, in commenting on these results, wonders how much of the incomes are derived from the profession of medicine and how much from investments in o If one could believe such prosperity to be shared l graduates from other schools the source of the endowments would not be difficult to discover.

MEDICAL MUNITIONS IN WAR.

THE United States of America have already arrang for the prompt supply of the surgical instruments whi would be needed by the Army should large-scale warfa ever break out again.[1] France is similarly planni ahead, for, as M. R. E. H. Salkin[2] points out in a rece article, surgical instruments are just as important munitions, and the medical department must set in peace-time their patterns, the number that w be wanted, and the depôts in which they are to stored and looked after. It must also arrange f their repair in war and for the replenishment stocks without interference with national productio A census of the surgical instrument industry France has, therefore, been taken. The instrumen are made at three chief centres: Paris, Noge (Haute Marne), and Thiers (Puy-de-Dôme). In Pa are particularly produced instruments of precisio at Nogent knives, scissors, and forceps; at Thi bistouries and cutting instruments. It is in th centres replacements will in war-time be made; repa will be done in other large manufacturing centr Sufficient quantity of the various grades of crucib steel, the raw material of the instruments, must planned for. In 1000 parts of steel 10 to 7 pa of carbon are required for bistouries, 5 to 4 for chise burrs, and the like, 3·5 for forceps. Stainless chro steel is being examined and has given good results far, but has not yet been officially adopted. T industry is carried on largely at home or in sm workshops, but sometimes in factories, and arran ments are being made to give it more protecti France exports at present three-fifths of her producti especially to the Latin countries. English steel, t writer admits, is excellent, but he finds the Engl surgical instruments a little large and less delicat finished than French. France is, however, backwa in suture needles and dental equipment, though th are being encouraged. Surgical instrument maki should, he concludes, be scheduled as a natio industry.

RED CELL AND HÆMOGLOBIN NORMALS

THE statement that the average number of r cells in the human being is 5,000,000 per c.mm. the male and 4,500,000 per c.mm. for the fem has figured in all text-books of medicine and in m special works on the blood and its diseases for the l 75 years. Its tacit acceptance is, as we have alre pointed out,[3] something of a mystery. Proba it will outlast the century, and this in spite of t fact that everyone accustomed to performing bl counts habitually encounters figures far outside t range in normal persons. In 1926 E. E. Osgoo showed that for normal men the figure should be the neighbourhood of 5,500,000 per c.mm.; same author, in collaboration with H. D. Haski has now investigated the blood of normal wom between the ages of 18 and 30, and again it is fou that the hallowed text-book statements are wide the truth. Using a carefully standardised techniq these workers find that the average red cell count healthy women between the ages stated is 4,800,0 per c.mm., 90 per cent. of their subjects giving readi between 4,300,000 and 5,300,000. As regards hæmoglobin percentage, Osgood showed in investigations upon the blood of males that average weight of hæmoglobin is actually 15·76 per cent., while the majority of methods in use in country and in America are based upon an assum 13·8 g. per cent. Curiously enough, the aver

[1] THE LANCET, 1926, ii., 1230.

[3] THE LANCET, 1926, ii., 191.
[4] Osgood: Arch. Int. Med., 1926, xxxvii., 685.
[5] Osgood and Haskins: Arch. Int. Med., 1927, xxxix., 64

entage of hæmoglobin by weight in the blood of en as estimated by Osgood and Haskins approxi- es closely to the accepted standard, being 13·7 per . The majority of hæmoglobinometers in use in country give readings in percentage of normal , but according to the results obtained by Osgood Haskins this figure is the normal for females and for males. Hæmoglobin percentages obtained he Haldane, Tallquist, or Dare methods would, hese findings, require an addition of about 15 per . to bring them up to the normal male standard. stigation of the total volume of packed red in female blood showed the average bulk to be cm. per 100 c.cm. of blood as opposed to 45 c.cm. nales. Calculation of the volume coefficient h gives an index to the actual size of the individual cell and may be defined as the volume of red per 100 c.cm. calculated to a red cell count of),000 gives a coefficient for the female of 42·8 as sed to 41 for the male. This difference in the me coefficients of male and female red cells would to be only explicable on the assumption that the of the red cell in the female is greater than in male. This is an observation which appears to eluded previous workers and obviously demands ier investigation.

LOW BLOOD PRESSURE.

HILST hyperpiesia and its consequences are the ect of limitless investigation and inquiry, the site condition, in which the blood pressure is ually low, is not written about very frequently ; pt in occasional conditions, such as severe surgical k and Addison's disease, the symptom of hypo- ion has seldom been given careful consideration. accordingly of interest to receive the exhaustive ograph on the subject recently contributed to American contemporary, *Medicine*,[1] by Prof. d Friedlander, of Cincinnati University. His lusions do not suggest that any very important s have been lost sight of. One large insurance pany in the United States, on reviewing 3389 ns of all ages in whom the maximum systolic d pressure was below 100 mm., found that these ed exceptionally good insurance risks, their al mortality being only 35 per cent. of that cted, whereas the company's general mortality 80 per cent. of the expectancy. In almost all severe infective fevers, including typhoid, pneu- ia, influenza, diphtheria, and scarlet fever, a ressive fall of blood pressure has been observed ng the acute period of the disease, and in influenza fall often goes on during the convalescent period ; hypotension is nearly always an indication of cardial involvement, but loss of vasomotor and reduction in the volume of blood in the r are additional factors, especially in influenza. hypotension of Addison's disease naturally pies a prominent place in any discussion of this ; indeed, the relationship between adrenal rity and changes in the arterial tension appears e at once the chief clue and the principal source ontroversy in all blood pressure problems. The iant clinical observations of Thomas Addison, e without the help of sphygmomanometers, iocytometers, or any of the complex armamentarium nodern scientific workers, have not yet been wed by any satisfactory explanation of the otension which is, perhaps, the cardinal physical in this disease. Chronic inflammatory processes, cially those affecting the teeth, accessory nasal ses, tonsils, gall-bladder, and uterine adnexa, very often accompanied by low blood pressure, Prof. Friedlander is of opinion that the sign is of genuine diagnostic value. Reviewing the ts of tissue extracts in producing an artificial otension, it seems clear that histamine, which is idely distributed constituent of animal tissues, t the only extractive capable of producing a fall in blood pressure. Parathyroid extract and various hepatic extractives other than histamine and cholin are amongst the more important bodies recently investigated. Apart from the nitrite group there are few drugs having any useful hypotensive action, but cucurbocitrin, the active principle found in water-melon seeds, and glucose given intravenously, are amongst those which appear to be genuinely effective, and further research may show them to be very useful in this connexion.

DRIED EGGS AS FOOD.

THE peculiar physiological or rather pathogenic effects of dried egg-white observed by Miss M. A. Boas in the course of experiments[1] on rats at the Lister Institute show what very great care is needed in feeding experimental animals on diets which are more or less artificial in character. They also suggest the question whether dried eggs should in any case form a large item of diet, although it does not follow that what is unsuitable for rats is not good for man. Dried egg-white used as the principal source of protein for young rats leads to eczematous dermatitis, beginning at the corners of the mouth and afterwards spreading, loss of hair, spasticity of the limbs, a kangaroo-like posture, loss of weight, and death, followed rapidly by rigor. These symptoms seem to be produced by any dried egg-white and are not peculiar to the predominant Chinese article. Even when dried at ordinary temperature in vacuo egg-white produces this effect, so that neither temperature nor preservative is the cause. Egg-white denatured but not dried by heat is harmless. Both potato and arrowroot starch furnish some unknown substance which neutralises the effect, whilst cereal starches do not. This protective factor is associated with, but apparently differs from, the water-soluble vitamins—the antineuritic substance and Goldberger's anti-pellagra body. The previous growth of the young rat and the antenatal diet of the mother may have a considerable retarding effect on the setting up of the morbid condition described. The explanation of the results is yet to be found. These observations, like many others, raise the question of the safety of depending, as civilised people seem more and more inclined to do, upon dried, tinned, sterilised, and otherwise preserved foods. They at least indicate the wisdom of including in any diet a large proportion of food which has undergone the minimal amount of preparation consistent with cleanliness and digestibility.

HOSPITAL COÖRDINATION.

DURING the last few weeks many converging events have focused attention upon the future of the voluntary hospitals and their relation to the municipal institutions. The subject has been discussed by the British Hospitals Association and the British Medical Association at Edinburgh on lines which suggest a general consciousness that the existing situation lacks permanence and that changes, not yet very clearly defined, in our hospital system are inevitable at no distant date. Prof. Hey Groves, in describing its shortcomings, has been particularly drastic. For years past he has declared it has been moribund and is being painfully kept alive by artificial expedients. Hospital buildings are out of date and badly placed, their equipment is necessarily incomplete, and their resources are insufficient to enable them to keep pace with the demands of the population—demands which are growing with embarrassing rapidity. The professor of surgery in Bristol University sees no way out of the financial difficulty short of State-aided insurance with a municipal and county rate to which the State would contribute an equal amount. This would involve Government control through a central hospital board, which would coördinate the entire hospital system of the country. In all this there seems to be some exaggeration of defects, a minimising of the patent advantages of voluntaryism, and an almost complete

ignoring of the amazing resiliency exhibited by the system since it began to recover from the shock of war.

These destructive criticisms, moreover, interesting and stimulating as they are, leave untouched the line of reform and coördination so regularly advocated in these columns to which particular attention was directed at Edinburgh during discussions on the future relationship of municipalities to the voluntary hospitals. On this subject there is a very large measure of agreement. In advocating the fusion of voluntary and rate-supported hospitals, Mr. H. L. Eason laid stress upon the fundamental factor of medical education. A teaching hospital must be able to admit every type of case, and fusion would facilitate rapid turnover and would enable the municipal hospitals to have a larger proportion of chronic cases. Many of those hospitals are admirably equipped and staffed; the best of them, indeed, range closely alongside the premier voluntary institutions. But they are isolated from the general hospital system both as regards medical teaching and the reception of patients. Their beds, too, are often standing idle while those of almost every voluntary hospital in the country are not only full, but besieged by waiting crowds. The wastefulness of such an arrangement is glaring, and the time has clearly come for its revision. Two hospital systems existing side by side, with no door of communication, but with a socio-economic barrier between them, are so anomalous that, in the new situation that has arisen since the war, it is impossible to defend it. It is fairly obvious, however, that it would be impossible to stop at the mere removal of barriers crying out for demolition. The process would leave gaps that could be filled only by a somewhat delicate process of repair. "Coördination" is a blessed word, but its virtues lie not in its mere repetition as a magical formula, but in a reasonable appreciation of its spirit and in its deft application in particular circumstances. Coördination between the voluntary and the municipal hospitals is a certainty of the not distant future, but when it comes about we must be prepared for a pitched battle between the advocates of Government control and tax and rate aid for the entire hospital system and those who are anxious to preserve all that is precious, human, and pitiful in voluntaryism. The voluntary hospitals are fast ceasing to be mere charities and are developing into highly important media of self-help, as witness the innumerable contributory schemes and other methods of supplementing charity by coöperation which, despite their vigour, are still in their infancy.

When these great questions definitely come up for settlement much will depend upon the attitude of the voluntary institutions. Speaking the other day to the British Hospitals Association as its President, Sir Arthur Stanley uttered a statesmanlike warning against aloofness from real reform. The hospitals, he said, must be prepared for "readjustment, correlation, development." That is not to say that they must necessarily become a mere department of the national administration. Linked together under some central control which would redistribute strength and prevent overlapping and duplication, and yet do its spiriting gently, the voluntary hospitals would have the satisfaction of knowing not only that none of their efforts was being wasted, but that many of them were being reinforced. Moreover, free intercommunication between the voluntary and the municipal institutions would distinctly ease the financial situation. It is assuredly not beyond the wit of man to readjust, correlate, and develop, to use Sir Arthur Stanley's crisp and useful phrase, without destroying the historic basis of our hospital system. That basis, which began with pure charity, is rapidly developing, as we have said, into self-help and coöperation. Both of those things are virtues of a highly practical character, and to wave them aside in favour of some symmetrical theory would be to flout some of the best instincts of mankind.

PROF. RUDOLPH MAGNUS.

NEUROLOGY owes much to Prof. Rudolph Mag whose death at Pontresina we have already recor He was only 53 years of age, but his fame long passed beyond the University of Utrecht, wher was appointed to the chair of pharmacology some before the war. His earlier work covered a wide f but his name will always be associated mainly an intensive study of posture carried out du the last 22 years of his life. His aim was to di the physiological functions of the eyes, labyri otoliths, neck-tissue, and lateral end-organs of body in so far as they contribute to the mainten of normal posture, and in this intricate researcl precision was remarkable. The attention whic gave to detail amounted to genius and has res in an important increase in our knowledge of function of structures that have long been fan anatomically. Starting with the reflexes of the s animal, Magnus and his collaborators went on to s the attitudinal and "righting" reactions of ani in which less and less of the brain had been destr Twenty years were devoted to research on the ph mena provided by the decerebrate animal (mid-l level), and at the time of his death further work in progress on those of the so-called thalamus an in which the cerebral cortex, pyramidal tracts, corpora striata are out of action. One of the re of all this investigation has been to show that equilibrium is upset the mechanism by which restored is purely reflex; the righting and tudinal reactions of animals are wholly involun and subcortical mechanisms furnish normal sta positions for each new cortical action. The ex ments leading to this conclusion were ably desc by Prof. Magnus in the Cameron Lectures[1] of and, as we pointed out at the time, it is permis to suppose from his results "that volition ma eventually driven to the highest transcortical level that a part at least of cortical activity may be s to be of an involuntary character."[2] To go fu than this is mere speculation, but Prof. Ma has appreciably narrowed the territory of vo as previously recognised. His untimely death a career which has included some of the finest n logical work of the present century.

Sir James Michelli is resigning the secretar of the Seamen's Hospital Society which he has for 40 years. When he took office the income Society averaged £12,000 per annum; it now ex £80,000, and six establishments are maintain the Society instead of one.

THE twenty-ninth annual report of the Metrop Asylums Board, which has just been issued, with the year ended March 31st, 1927. The m portion occupies 300 of the 420 pages and is di into four sections—infectious diseases, mental dis tuberculosis, sick children—each of which c obtained separately, price 1*s*. The whole rep obtainable for 5*s*. from the offices of the Victoria Embankment, London, E.C. 4.

CONDENSED MILK.—The Minister of Health is to make regulations amending the Public Health (Con Milk) Regulations, 1923, so far as they relate to the la of condensed milk. Copies of the draft regulations obtained under the description "Draft, dated Augu 1927, of the Public Health (Condensed Milk) Amer Regulations, 1927," from H.M. Stationery Office, Kin London, W.C. 2 (price 1*d*.). Any representations subject should be addressed to the Secretary to the M at an early date.

Modern Technique in Treatment.

Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCXXXVI.

THE TREATMENT OF SINUSES.

I. General Considerations.[1]

"A sinus is not a disease but a symptom." Successful treatment therefore depends on the diagnosis and removal of the cause, and is not merely a question of the use of some special irrigation, or vaccine, or artificial sunlight, or ionisation, or the injection of some paste, or in fact any of the very numerous methods that are often more or less indiscriminately employed. All these methods have their place in the treatment, but they must only be used with relation to the cause in any particular case. To treat a surgical sinus with artificial sunlight may often be quite appropriate, but it is a gross violation of surgical principles to use a vaccine for the cure of a sinus over the jaw instead of removing the buried fragment of tooth which is so often the causative factor.

Most sinuses can be classified under one or other of the following heads :—

1. Foreign bodies derived from the outside.
2. Foreign bodies derived from the tissues themselves, such as dead bone, or teeth, or calculi.
3. Defective drainage of abscess cavities.
4. Communications with a secreting epithelium.
5. The persistence of some vestigial structure.
6. Tubercle or actinomycosis.
7. Malignant disease.

Sinuses are said to be *active* when the cause remains, and are spoken of as *residual* when the track persists, despite of the fact that the original causative factor has been effectively dealt with.

Sinuses due to Foreign Bodies.

We must now consider some of the varieties of sinus in detail, and first *those due to foreign bodies which have entered the tissues from without.* The commonest examples are associated with missiles, which everyone became so familiar during and since the war. Even at this late stage it is necessary to insist on the routine X ray examination of every wound in which there is the remotest possibility that a metallic foreign body may be the cause of a sinus. The discovery of such a foreign body is usually easy, but it may be found at some considerable distance from the orifice of the sinus which it is causing, and the X ray may have to include a large field. The removal of such a foreign body will cure a sinus due to its cause. Removal may be carried out via the old sinus, but it is often very much easier and quicker to cut directly down on to the foreign body by a shorter and more direct route. There are some cases in which the sinus persists even after the removal of the foreign body. This is not uncommonly due to a small portion of clothing which has been carried into the tissues at the same time as the metallic fragment, which has escaped removal. There are also many foreign bodies from without which do not show on X ray examination, and yet may be large and troublesome, such as thorns or pieces of glass. The history should be closely scrutinised, and exploration may have to be carried out for their detection and removal.

Another class of external bodies are those introduced in the carrying out of some surgical operation. In the days when silk was more commonly used for sutures and sutures, it was often the cause of troublesome sinuses which persisted until some offending suture was either extruded naturally or removed. In a case of persistent abdominal sinus I removed a piece of silk ligature used to secure the pedicle of an ovarian cyst seven years previously. Silver wire and catgut, and even heavily chromicised catgut, may likewise be offenders. Drainage-tubes are every now and again lost in the tissues, and have been known to be the cause of persistent sinuses resulting from empyema, appendix abscess, necrosis of the long bones, &c. Sometimes a rubber tube retained for too long in a wound may itself be the cause of an indolent sinus. Fragments of gauze or cotton-wool may also be overlooked, and in one striking case a troublesome sinus of three years' standing in connexion with the upper jaw proved to be due to a small piece of sponge which had been packed into a tooth socket and had been forgotten.

Foreign bodies derived from the tissues themselves are sufficiently numerous and important, and among these fragments of bone in the form of sequestra, and teeth or portions of teeth, supply the commonest examples. There is no end to the sinuses about the jaws which turn out to be due to diseased teeth or fragments of teeth left behind after extraction, roots driven into the substance of the jaw as the result of unskilful attempts at extraction, or roots which have been left behind, have healed over, and have given rise to sinuses even years afterwards. Sequestra are such well-known causes of sinuses that they are not likely to be overlooked, but it must be remembered that even a very small sequestrum will sometimes be the cause of a persistent sinus, and that the orifice of the latter may be at some considerable distance from the focus of diseased bone. Other foreign bodies, such as calculi, may be the cause of sinuses, and I have removed gall-stones which have been the offenders. In one notable case an enterolith from the appendix kept up a sinus for 40 years, the causation being proved by the cure which immediately followed its removal.

Defective Drainage of an Abscess Cavity.

Sinus may be due to the defective drainage of an abscess cavity, such as an empyema in the chest, or the similar condition in the antrum of Highmore. In the chest, the situation of the opening is only one of the factors that has to do with the persistent opening, but it may be the main one, as in those cases of empyema which have burst spontaneously somewhere in the neighbourhood of the nipple or have been deliberately opened too high up. The immediate requirements of the case are met, and the patient's condition improves, but the sinus persists because only the top of the collection of fluid has been tapped, and it requires an incision in a more dependent place to bring about proper drainage of the cavity and to hold out prospect of cure of the sinus.

Communications with a Secreting Epithelium.—Persistent Vestigial Structures.

Sinuses due to communications with a secreting epithelium include those most commonly found about the anus, which we speak of as "fistula." These persist because of their communication with the bowel. Sinuses due to vestigial structures are most frequently found in the middle line of the neck, where the thyroglossal fistula is a classical example, or in the side of the neck in the situation of the branchial clefts. They may also occur between the anus and the coccyx, where postanal dermoids are found. The clue to the exact nature of the latter type may be furnished by the appearance of hairs or even a tuft of hair which may project through the opening.

Sinuses due to Tubercle.

Then there are the sinuses in which tubercle is the cause. The opening on the surface may communicate with a deep-seated focus either in connexion with a tuberculous gland, as in the neck, with bones and joints, or occasionally with the peritoneal cavity, as in those troublesome sinuses about the umbilicus or the right iliac region where the primary disease is in the bowel. Sometimes the track itself is not actually tuberculous but is merely a communicating channel of granulation tissue between the tuberculous focus and the surface, but more usually the track is actually engrafted with tubercle, and it is these sinuses which furnish the majority of the residual sinuses which have been mentioned.

[1] The article by Prof. Grey Turner on the Treatment of Sinuses in Special Situations will appear in this series next week.

In the same situations actinomycosis may be the causative factor.

Malignant Disease.

Malignant disease is one of the rarest causes of sinus, but it must be borne in mind. In this connexion it is as well to mention that sinuses of long duration, perhaps usually associated with very deep-seated and chronic bone disease, may eventually themselves become engrafted with epithelioma, although this is a very rare event.

The Indications for Treatment.

A sinus should never be allowed to persist without an attempt at its diagnosis and cure. It is not only an annoyance, but a potential source of danger, because it may be a focus for continuous septic absorption and it is liable to outbursts of acute infection. Chronic absorption may lead to a whole train of evil symptoms, sometimes even culminating in lardaceous disease. Tetanus has been known to arise and malignant disease may certainly follow. For these reasons every sinus requires careful investigation :—

1. By ascertaining the history accurately and by critical consideration of all the circumstances.
2. By ordinary examination with the object of ascertaining its relation to surrounding parts.
3. By X ray examination, in some cases with the aid of opaque injections.
4. By cautious use of the probe.
5. By noting the effect of treatment.
6. By reconsideration from time to time.

From what has been said it is clear that the most important indication is to discover and remove the cause, and if this is done the great majority will soon heal.

G. GREY TURNER, M.S. Durh., F.R.C.S. Eng.,
Professor of Surgery in the University of Durham ;
Surgeon, Royal Infirmary, Newcastle-on-Tyne.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt.-Comdr. (D) T. A. B. Corless is placed on Retd. List at own request.

Surg. Lt.-Comdr. A. W. Gunn to be Surg. Comdr.

Surg. Lt. A. H. Harkins to be Surg. Lt.-Comdr.

The following appointments are notified :—Surg. Comdr. : C. H. M. Gimlette to *President*, addl., for three months' post-graduate course. Surg. Lt.-Comdrs. : A. W. McRorie to *President*, addl., for three months' post-graduate course ; F. C. Hunot to *Yarmouth ;* and W. E. Heath to *Fisgard ;* L. S. Goss to *Suffolk ;* and J. C. Brown to *Vivid*, for *Rodney*. Surg. Lts. : N. A. Dickinson to *Hermes ;* and L. P. Spero to *Adamant*.

ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg. Sub-Lts. F. T. Doleman and A. R. Thomas to be Surg. Sub-Lts.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. J. H. R. Winder retires on ret. pay.

Capts. to be Majs. : T. Menzies, D. H. Murray, E. Underhill, R. A. Mansell, and J. T. Scrogie.

Lts. to be Capts. : C. R. Christian, C. W. Greenway, R. J. Rosie, J. Huston, and E. G. Dalziel.

ROYAL HOSPITAL, CHELSEA.

Physician and Surgeon : Maj. E. A. Strachan, vice Maj. E. T. Potts, C.M.G., D.S.O., who has vacated the appt.

REGULAR ARMY RESERVE OF OFFICERS.

Col. T. C. MacKenzie, late R.A.M.C., having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY.

Lt. A. H. Macklin to be Capt.

E. J. G. Glass (late Offr. Cadet, Edinburgh Univ. Contgt., Sen. Div., O.T.C.), F. Lishman, J. N. Russell, F. Heywood-Jones, and M. S. Scott to be Lts.

The King has conferred the Territorial Decoration upon Lt.-Col. Andrew Johnstone Brown and Majs. Henry Neville Burroughes and Ronald Ogier Ward.

ROYAL AIR FORCE.

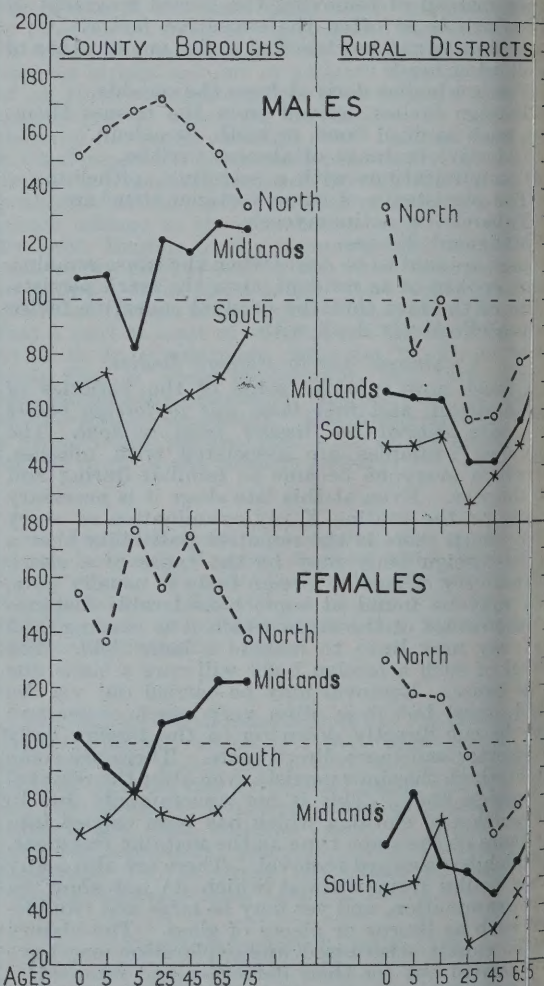
Squadron Leader F. C. Jobson relinquishes his commission on completion of service.

Special Articles.

THE GEOGRAPHY OF MORTALITY FR BRONCHITIS AND PNEUMONIA.

NEARLY one-seventh of deaths from all ca come under the two rubrics of bronchitis and p monia, and a study of the incidence of these dise which the Registrar-General's report[1] renders poss is therefore of great importance. Such a study l inevitably to the conclusion that a large par mortality from these diseases is avoidable. A of the teaching of Tables XLVI. and XLVII. in report can be seen graphically displayed in Fig and 2. These diagrams show for three division England the male and female death-rates for years 1921–25 from bronchitis and pneumonia res tively at each of seven age-periods, in proportio the mortality for the same ages in England Wales stated as 100.

FIG. 1.



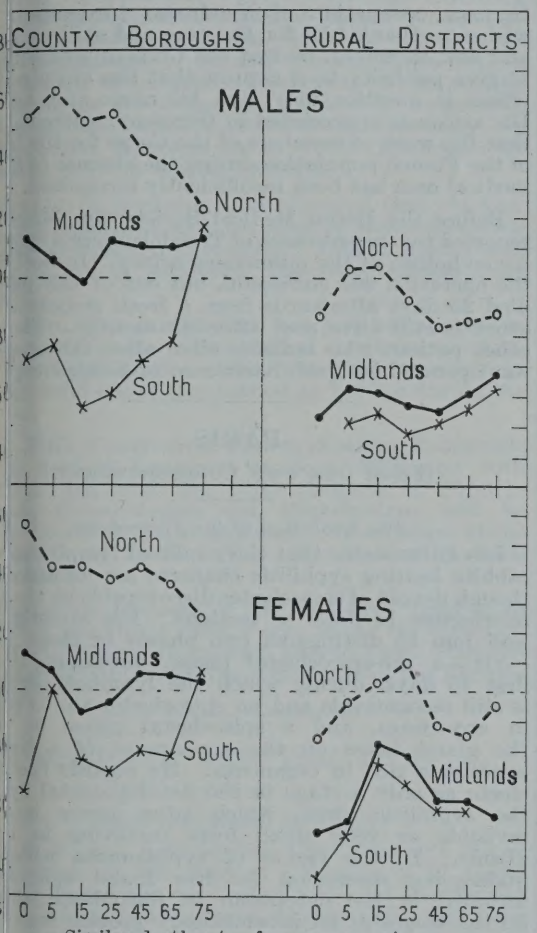
Death-rates from bronchitis showing topographical varia

County boroughs and rural districts in each of sections of England—north, midland, and sou are contrasted in each instance for males and fe separately. Wales has been omitted from the parison, but it may be stated broadly that it is surpassed in its unfavourable mortality by north of England. It will be seen that in co

[1] The Registrar-General's Statistical Review of Englan Wales for the year 1925. Text. H.M. Stationery Office.

ghs, both for males and females, the death-rom bronchitis is much higher in the north than e midlands, and higher in the midlands than south at most ages. The same excess is shown al districts in the north, though on an appreciably scale. Similar remarks apply to the mortality pneumonia, with differences in detail which e best studied in the diagrams.

FIG. 2.



Similar death-rates from pneumonia.

y should the population in the northern areas, particularly in urban districts, thus suffer sively? One naturally thinks of the severe tic conditions of the north, of its excessive ll and humidity, of its deficiency in sunshine, f its fogs. These might be assumed to apply both an and rural districts; but the diagrams show although rural, like urban, mortality from these es is excessive, the rural excess is at a much absolute level than the urban. Taking the s for males the relative death-rates at ages n county boroughs in the north and south ctively for bronchitis are as 152 : 84, and in districts in the north and south respectively are 3 : 47. At ages 25–45 the corresponding figures 72 : 60 and 56 : 26. Similar differences can be l in the figures for pneumonia. It is clear that te does not form an adequate explanation of differences between north and south, nor of ifferences in north and south between towns and ry districts. That climate does not form an nate explanation is further indicated, as pointed n the Registrar-General's report, by the figures h show that the infant diarrhœa rate of the north re than double that of the south, that of the nds being intermediate in regard to both hœa and respiratory diseases. Here are the figures for diarrhœa in the north and south respectively:—

		County boroughs.	Rural districts.
Relative death-rates from diarrhœa and enteritis, that of England being stated as 100	North	154	85
	South	63	32

Diarrhœa in large measure, given other equal conditions, is a measure of summer temperature. Yet the north suffers excessively from it. As stated in the Registrar-General's report, simultaneous excesses of 74 per cent. for mortality supposed to be promoted by cold and of over 100 per cent. for mortality known to be promoted by heat cannot both be explained on the score of climate. It is evident that conditions other than climate are not equal; and that in regard to diarrhœa, as in regard to bronchitis and pneumonia, evils exist to an extent which is not equalled in the midlands and still less in the south. What are these? Do industrial occupations explain the difference? If so, the excessive mortality from bronchitis and pneumonia ought to occur chiefly at the working ages of life; whereas the diagrams show that it is great at all ages, and in rural districts is greatest in childhood for bronchitis. That industrial occupations, although doubtless concerned, do not give the chief key to the situation is especially indicated by the differences found between the bronchitic mortality of children under 5 in north and south. In the north this is 152 : 133 for male children in county boroughs and in rural districts respectively; and 68 : 47 in corresponding parts in the south. Here evidently occupational evils are not primarily concerned.

It may be safely stated then that quite irrespective of differences in climate or in occupational conditions there is a terrible excess of bronchitis and pneumonia in northern districts, rural as well as urban, though especially in urban districts. That this difference is not due in the main to unfavourable climate is further shown by the fact that in summer these same northern districts, rural and urban, have an excessive diarrhœal death-rate, although the summer temperature in the north is much less favourable to epidemic diarrhœa than that in the south. There is needed more detailed local analysis both of northern, midland, and Welsh figures, by means of which it would be practicable to bring out possible important differences in the incidence of these diseases. Meanwhile it may be taken as almost axiomatic that all that is involved in the word "sanitation," and in the standard of housing and of life in general, are lower and less satisfactory in the north than in the rest of England; and this general conclusion should cause searchings of heart and serious efforts at generalised reform on the part of public health authorities throughout the crowded industrial and rural districts of the north.

Official Recognition of "Natural Medicine."

THE parliament of Thuringia has granted the sum of M.100,000 (£5000) as a first instalment towards the construction of a State clinic for natural medicine in Jena. This has led to a protest by the medical faculty of Jena University, in which it is shown that so-called natural medicine is not a special science, and that its methods—so far as they are valuable—are used by the medical profession. The faculty points out that it would be dangerous to patients of the clinic if these methods alone were employed for the treatment of disease, to the exclusion of others which long experience has shown to be useful. Exception is taken to the Government's action in adopting the plan without asking the opinion of the medical faculty of Jena or the medical chamber of Thuringia. The money spent on the new clinic would, it is thought, be more usefully devoted to improvement of the old

university clinics of Jena and to the construction of new houses for which there is urgent need.

Workmen's Insurance in Various Countries.

In the Journal of Industry and Statistics a report is published on workmen's insurance abroad. According to the writer, the longest established insurance is that of Germany where a sickness insurance Act was passed in 1883, an accident insurance Act in 1883, and an Act for insurance against old age and invalidity in 1911. In Germany 32 per cent. of the population are insured, in Great Britain 35 per cent., in Austria 25, in Norway 21, in Czechoslovakia 16, in Poland and Russia 6, in Jugoslavia 4. In Luxemburg, Rumania, Latvia, Japan, and Greece insurance covers only industrial workmen, leaving out other classes of the working population. Certain countries have only voluntary insurance against sickness, assistance being given by the State. These include Belgium, where 8 per cent. of the population are insured in this way, Denmark with 4 per cent., Finland with 18, France with 7, Sweden with 12, and Switzerland with 23. There is no State insurance of any kind in the United States of America.

Public Health in Russia.

The Society for the Study of Eastern Europe recently arranged a series of lectures by Russian savants in Berlin. Their leader was Prof. Semachko, Commissary of Health of the Union of Soviet Republics, and he gave an address on the Institute of Social Hygiene and its work. By the introduction of compulsory vaccination five years ago the amount of small-pox had, he said, been considerably reduced, whilst cholera and enteric had also become less common of late years. The general mortality had fallen from 27·3 per 1000 in 1913 to 23·7 in 1925. The number of births had not decreased, notwithstanding the liberal law on artificial abortion, and was almost the same in 1924 as in 1913. The annual increment of population had risen from 16·5 in 1903 to 21·5 in 1925.

Death of Prof. Fritsch.

The death has occurred, at the age of 90, of Prof. Gustav Fritsch, a pioneer in the physiology of the brain. As early as 1870 he discovered, with the late Prof. Hitzig, that the cerebral cortex could be excited by the faradic current, a fact upon which the localisation of the motor centres was based. His scientific interests were from the beginning very wide. Shortly after qualifying in 1863 he went for three years to South Africa on an ethnographical survey of which he published a description. Soon afterwards he went to Aden on an expedition to observe an eclipse, and thence travelled into upper Egypt upon anthropological and ethnographical pursuits. After his return he made studies on the anatomy of the diatoms and on electric fishes, and was appointed head of the department of biology and microscopy at the newly founded institute of physiology at Berlin University. His last work was on the comparative anatomy of the retina in the different human races, and was the result of travels which had led him to America, Eastern Asia, the Southern Seas, and Australia. In spite of great difficulties he managed to test the vision of many natives and to secure for microscopical examination specimens of the retinæ of those who had just died. He discovered that the acuity of vision of Europeans was on an average much lower than that of the natives of Java, India, and Mongolia, and that this fact was connected with the structure of the fovea centralis.

Health Week.

Last year's Health Week was so successful that it has been repeated. This time the propaganda was chiefly done in rural districts, and the campaign's main object was the destruction of vermin in its relation to stables, dwellings, and food. Each district formed a committee under the presidency of the district medical officer of health, the members including medical men, teachers, clergymen, and officials of sick-clubs. Pamphlets and picture post-cards distributed in schools, and lectures were deliv by the teachers. The clergy were asked to alluc Health Week in their sermons; in chemists' s the means of destroying vermin were exhibited, w broadcasting stations and the local press exerted influence for the success of the campaign.

A well-known French scientific man is tryin ascertain the name of an officer of the German A Medical Corps who attended his parents during German occupation of Vendresse (Ardennes). wishes to thank him for the care and skill exerc and has, therefore, invited the German medical to give publicity to a request that the army me officer in question may give his name and add His action is appreciated in Germany, where it is that the work of members of the Corps for the be of the French population during the absence of Fr medical men has been insufficiently recognised.

Before the Berlin Medical Society Dr. Meyer reported two recent cases of Trendelenburg's oper for embolism of the pulmonary artery. In both the operation was successful, but one of the pat died 25 days afterwards from a fresh embolus. other is still alive now after six months. The other patient who remains alive after the oper was operated by Prof. Kirschner, of Königsberg.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Evolution of the Spirochæte.

LEVADITI states that the popliteal lymph glan rabbits bearing syphilitic chancres are infective though devoid of spirochætes discoverable by the microscope in films or sections. His investiga lead him to distinguish two phases in these g —viz., a pre-spirochætal phase, developing in first 45 days, during which the lymphoid stru is still recognisable and no spirochætes are to be in any form, and a spirochætal phase in v the gland takes on the appearance of a pri syphiloma rich in organisms. He regards the s chæte as only a stage in the developmental cy the syphilitic virus, which later passes into invisible or very small form occurring in ly glands. In the region of syphilomata which undergoing resorption he has found spiroch included in the cytoplasm of fibroblasts, sh all the stages of an involutionary process tendi the formation of almost invisible granules. conception of changing form is invoked to ex (1) latent syphilitic infection with the presence virus in certain tissues not containing spiroch (2) cases of general paralysis of the insane or occurring without demonstrable spirochætes in nervous system; and (3) relapses coming on in of treatment, the resting forms being, he th more refractory to chemotherapeutic agents that spirochætal vegetative forms.

Yellow Fever and Bismuth.

The action of bismuth upon *Leptospira icte* (regarded by Noguchi and others as the infecting in yellow fever) has recently been studied by Sa Hosaya, and Stephanopoulo. They find that t bismuthate of sodium has a curative and proph action in guinea-pigs infected by the spirochæte this seems to be identical with the action of the compound on *Spirochæta icterohæmorrhagiæ*. research has shown that there is a close an between the two organisms, and perhaps these in gations may lead to yellow fever being treated derivatives of bismuth.

Application of Ultra-violet Rays.

The local use of ultra-violet rays is often hin by the difficulty of bringing the end of the appli which consists of a rod of rigid quartz, into

on with the lesion. Dejust has devised a ication in which the rod consists of segments in touch with one another, the whole forming in which can be bent at will. Investigation of ew device at the Optical Institute shows that e and ultra-violet rays pass along the chain, is claimed that it will allow irradiation of regions e body which have hitherto been inaccessible.

Leprosy in French Guiana.

ernadie reports 300 cases of leprosy at Cayenne, e population is about 12,000. Among the 0 inhabitants of French Guiana there are, he 800 or 900 lepers. Contagion occurs mainly ntact in the home, at schools, or in prisons. nged and intimate contact is necessary for ion, and it takes six or seven years for the e to develop among convicts.

razès, of Bordeaux, has observed that chicken-like small-pox and vaccinia, is sometimes com-ed by epididymo-orchitis. This is hardly sur-g if, as is supposed, the three diseases are d.

term "verdunisation" has just been coined in e to designate the method of sterilising drinking by hypochlorite. The name has its origin in ccessful use of the method at Verdun during the ar.

Fifth Congress of French-speaking Pediatrists e held at Lausanne on Sept. 29th and 30th Oct. 1st, and the Fifth Congress of French-ing Gynæcologists and Obstetricians will be t Lyons on the same dates. Information about tter may be had from Mr. Voron, 12, Quai , Lyon.

ourse on Diseases of the Digestive Tract is to ld at the Hôtel Dieu, Paris, under the direction f. M. Villaret, from Sept. 12th to 23rd. Particu-e obtainable from the secretariat of the Faculty dicine.

MEDICINE AND THE LAW.

Death Accelerated by Ether.

an inquest held at the City Coroner's Court ly 29th on the body of a woman of 27 years, ied during the removal of a lobe of the thyroid it was stated that gas, oxygen and ether were t given by Boyle's apparatus, chloroform being tuted when ether clonus developed. An ion of hyoscine had been given on the previous The anæsthetist giving evidence said that of wo brands of ether in use at the hospital were certified by the manufacturers to be and as an extra precaution both had been or analysis to the Medical Research Council, confirmed the purity with the exception "faint trace of deleterious chemical material" of them. The woman, it seems, had developed rous symptoms a year previously when under nfluence of ether for the similar removal thyroid lobe. Sir Bernard Spilsbury reported death was due to fatty degeneration of heart e (verified microscopically) consequent upon thalmic goitre and accelerated by ether given anæsthetic. The anæsthetist and the house n agreed with him as to the cause of death. oroner, in summing up, remarked that this was rst time in which a suggestion made in his l report for 1926 had been taken—namely, all anæsthetic ether should be analysed and ed as pure before use and kept after delivery t-proof amber-coloured bottles. This had been in the present case. A verdict of death from venture, the ether having been carefully and lly administered for a necessary operation, was led.

The Meaning of "Drunk."

While medico-legal experts continue to examine the tests of drunkenness, magistrates and juries from time to time apply some criterion of their own and reach decisions unassisted by any definition. Section 40 of the Criminal Justice Act of 1925 made it an offence to be "drunk while in charge on any highway or other public place of any mechanically propelled vehicle." At the recent Quarter Sessions for the county of Worcestershire, when a charge of this nature was being investigated, the chairman seems to have told the jury that, if a man had taken alcohol and was thereby rendered unfit to drive a motor-car, he was drunk "for the purposes of the present case." After this summing-up the jury evolved the following verdict: "Guilty of being incapable of driving a motor-car brought about by alcohol, but he was not drunk; he was not drunk to the extent which we should call a drunken man." The chairman took this to be a verdict of "Guilty," and proceeded to sentence the accused to one month's imprisonment in the second division. The Court of Criminal Appeal, however, has quashed the conviction. No amount of argument or ingenuity, said the Lord Chief Justice, was capable of getting rid of the fact that the jury said the man was not drunk. Drunkenness was a necessary ingredient of the offence; the verdict meant that that ingredient was absent. The chairman at Quarter Sessions had suggested that the word "drunk" should be defined in a particular way; the suggestion might deserve the attention of Parliament, but meanwhile this conviction could not stand. No definition or interpretation from the bench could turn "not drunk" into "drunk." Not long ago Mr. Justice McCardie was remarking that persons were certified insane without any definition of insanity. Evidently the law is content to rely upon the common meaning of words intuitively used and applied by jurymen. Thus the question "Was the accused drunk?" can be sufficiently answered "He was not drunk, not to the extent which we should call a drunken man."

Exorcising Evil Spirits.

The Allahabad correspondent of the *Times* reports an unusual defence to an accusation of murder. The accused, after having suffered for three months from dysentery, had consulted an exorciser of evil spirits, who assured him that his illness was due to a spell cast over him by a man named Hubba, who was under the influence of evil spirits. The accused thereupon killed Hubba with an iron-shod staff. This form of self-defence not being recognised by the criminal law, the accused was found guilty. The sessions judge is reported to have expressed reluctance to inflict the death penalty as the accused was virtually mad to think he could expel the evil spirits from the dead man by striking him with his staff. A sentence of transportation for life was imposed instead. Elements of demonology and witchcraft in criminal proceedings are by no means confined to India. A few years ago a court of appeal in East Africa quashed the conviction of a man accused of injuring his neighbour by putting upon him the evil eye. And even more recently a bench of magistrates in Devonshire was asked to accept a similar story.

CORRIGENDUM.—In the discussion on cerebellar function at the meeting in London of British and American neurologists (THE LANCET, August 6th, p. 302) we regret that Dr. F. M. R. Walshe's remarks are incorrectly reported. What he did say was that cerebellar ataxy was a phenomenon of voluntary movement, and was not present in the reflex movements of the thalamus animal without a cerebellum, and that Holmes had shown that the cerebellum had *no* sensory functions.

OLDHAM ROYAL INFIRMARY.—The Nook, Greenfield, has been opened as an auxiliary to the Oldham Royal Infirmary. Situated at the foot of Alphin Pike, one of the highest peaks of the Pennines, and splendidly equipped, the new hospital has been established by the generosity of the late Mr. J. L. Hargreaves.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some 1926 statistics for five county boroughs and one borough :—

Name of district and mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Heart disease.	Diarrhœa under 2 years	Infant mortality.	Maternal mort. from childbirth.
West Ham .. (315,900)	21·2	10·7	1·14	1·24	2·2	1·4	13·9	62	1·9

West Ham.

Dr. F. Garland Collins reports that in September a whole-time assistant was appointed mainly for maternity and child welfare work. An antenatal clinic has been started at the Silvertown centre and a new centre has been opened in West Ham-lane, where both antenatal and postnatal clinics are in operation. The work of the health visitors has been reorganised and an arrangement made with the Plaistow maternity charity to prevent overlapping and to promote coördination. Home helps are employed by the council, and work under the direct supervision of the health visitors. A list of approved women is kept at the town hall, and each home help is required to give prompt notice when she has undertaken a case. During 1926 there were 1453 applications for home helps and 1261 of these were granted. During the last four years about 100 tons per annum of dried milk has been supplied at cost price for the benefit of nursing and expectant mothers and children under 3. The milk is received in hermetically sealed canisters and packed daily in cartons, in order to make sure that it is in good condition. The Plaistow isolation hospital has been made available for cases of puerperal fever, but it is found that most of the cases are sent into voluntary institutions. So far the existing nursing associations have provided the nursing required, and it has not been necessary to appoint a municipal nurse. A panel of three consultants has been formed so that the notifying practitioner may have a choice of specialist when a second opinion is desired. A sanatorium for children suffering from pulmonary tuberculosis, with accommodation for 40, is now being built on the council's site at Langdon Hills. This will meet a long-felt want.

There is much flagrant overcrowding. No houses were built with State assistance during the year, but the council are at present erecting blocks of flats, four storeys high, capable of accommodating 152 families. It not infrequently happens, says Dr. Collins, that a tenant renting three rooms from a landlord will sublet two of them to two separate families. If there is only one w.c. much bitter feeling arises between the tenants owing to the ground floor kitchen being converted into a thoroughfare to the backyard.

During Health Week about 35,000 persons visited the exhibitions. Dr. Collins emphasises the importance of selecting lecturers who know something of the neighbourhood, and will thus avoid putting forward impracticable suggestions. He also stresses h danger of these exhibitions being exploited by r firms. The babel which ensues often tends to mini the true purpose of the exhibition. He suggest interval of more than one year between health we the best form of health propaganda, he consider steady persistent teaching in the schools and chur and through the press and in the homes and ha of the people. The residential open-air school 80 boys established at Fyfield has been at work two years without a single case of infectious dis or any serious illness ; it also kept free from epidemic of influenza which affected the bor towards the end of the year. Seven nurses at isolation hospital contracted scarlet fever and diphtheria. All new probationers are now tested if necessary, immunised against these diseases. results of Dick tests on scarlet fever cases wer follows : 66 of 71 patients tested in the first five of the illness were positive ; 48 of 87 tested on seventh day were positive ; 57 of 160 tested in second week were positive ; and 57 were retest weekly intervals. All had become negative by end of the sixth week except seven, who were pos on discharge from hospital.

Blackburn.

Dr. Oscar M. Holden tells us that Blackbur 1926 had the highest total rainfall of any large t in England, nearly 41 inches. The hours of b sunshine totalled 1114, which might be compared i the 1211¼ registered at Lytham. The chief indu is cotton-weaving and its subsidiary bran Normally 748 of every 1000 women and 280 of e 1000 men are textile workers, but the year has one of depressed industrial conditions with r unemployment. The respiratory group of dis bulks largely in the death returns, and Dr. Ho suggests that unfavourable climatic conditions, cou with a dirty atmosphere, are the predominant ca He suggests a connexion between the decline in t diseases and the cleaner atmosphere during the strike of last year. Respiratory diseases are mark more prevalent among the cotton operatives. Spin and unclassified operatives show the most unfa able figures. Winders and warpers are better pl Female weavers apparently come off better than r

About 50 per cent. of the babies born are exem from vaccination. A small outbreak of small-p a mild type gave rise to eight cases in the Qu Park Institution. It was attributed to an undet case in a vagrant. A small open-air school, prov beds for 20 delicate children, is carried on in o the original scarlet fever pavilions at the ope hospital. Ultra-violet light apparatus is also pro at the hospital for the benefit of the maternity child welfare, tuberculosis, and school departm Dr. Holden thinks that the practice of allowing visitors twice a week to see the diphtheria and sc fever patients is a mistake. Apart from the win cleaning business, managed by the Charity Orga tion Society for ex-sanatorium cases, there i system of after-care for consumptives, and Dr. H thinks such a system is greatly needed. The arr ments at the hospital for tuberculous patients considerable improvement. There is no dinin or recreation-room, all the meals being taken i ward. The records show that of the patients tr at the corporation hospital and discharged 1913, 13·4 per cent. are at full work with no symp and 5·2 per cent. at full work but with diffic The corresponding figures for the patients sen treatment to Meathop Sanatorium are 19·0 per and 6·8 per cent. respectively.

The antenatal clinic has two sessions in the and was attended by 480 prospective mothers. Holden complains that although 80 per cent. o confinements are attended by midwives the nu of cases sent by them to the clinic was only 59. municipal maternity home has accommodatio 20 cases, and the medical officer of health is empo to remit the minimum fee of £1 11*s.* 6*d.* per we

es of proved necessity. The patients admitted nbered 212, being 39 fewer than last year. Each nber of the staff is a fully-trained nurse as well a qualified midwife. Dr. Holden would have liked see more use made of the beds, and it is surprising t hospital treatment is not sought more often, ng that in 1926 27·3 per cent. of the confinements rivate houses took place in the kitchen or living-m. The number of stillbirths in 1926 was 4·8 per t. of the number of live births. The neonatal tality was 45·8 per 1000. There were 19 cases of thalmia neonatorum and one baby totally blinded. ensus taken in March, 1926, did not reveal any rtage of houses, which is not surprising when it is what a small difference there has been between birth-rate and death-rate in Blackburn of late rs. Individual cases of overcrowding met with e due either to bad distribution of the family in rooms or to subletting.

Northampton.

r. Stephen Rowland, formerly tuberculosis officer, took up his duties as medical officer of health in ember after the death of Dr. J. D. McCrindle. terial examination of the town's water as a rule ealed a high degree of purity, but occasionally this ndard was not maintained. The Monarch-road which was a source of complaint in 1925, caused her complaints in 1926 owing to the invasion of hbouring houses by crickets bred on the tip. tip is now disused and a comprehensive scheme n preparation for the collection and disposal of se refuse by modern appliances. Five samples of k taken from one farm were reported by the lyst to contain added water varying from 7 per cent. 9·3 per cent. The farmer successfully prosecuted ervant for adding the water and the summons nst himself was withdrawn. In the case of a ple alleged to contain 7 per cent. of added water magistrates were satisfied that the milk was sold t came from the cow.

sudden outbreak of scarlet fever occurred in the inning of November after a period of almost plete freedom from this disease. It was found t nine of the first patients had their milk from e retailers, but that these three obtained the milk n one wholesaler, who in his turn obtained it from rm outside the borough. A milker was found at farm who had been away ill for 12 days in the nd half of October. He exhibited, however, no s of scarlet fever after repeated examinations, his medical attendant had seen no signs or ptoms of scarlet fever during his illness. He was luded from work and the milk was pasteurised. hin three days of the pasteurisation there was a den drop in the notifications. There were about cases in the borough and neighbourhood, which e evidently due to the infected milk; but, as often pens in scarlet-fever-milk epidemics, it was ossible to show how the milk had become infected.

Lincoln.

r. H. Gordon Smith thinks the existing unemploy-t can hardly fail to affect the health of the mmunity. In dealing with the condition of the dren attending the centre he points out that 80 2·9 per cent.) suffered from marked rickets, while suffered from respiratory complaints, 148 from tro-intestinal disorders, and 82 from debility. out of 838 infants were bottle-fed at the time of first visit of the health visitor, apparently because mothers often were not in a fit state to nurse them. ny men have been unemployed for years, others working part time and the weekly wage is often than £2. In the family dietary white bread is minent, and potatoes, margarine, sugar, and tea are l to the fore. Meat is not a big item, and milk y average a pint per day for everybody. The baby, therefore, "will probably receive at home ng starchy food, just the sort to give it rickets." milk and other foods supplied by the maternity child welfare committee prevents things from g worse than they are. Of the 86 infant deaths 27 occurred in the first week and 46 in the first four weeks (a neonatal mortality of 42). Of the eight midwives three are municipal. The city maternity home provided for 260 confinements in the home and for 428 through the district service, the total births during the year being 1089. Sixteen antenatal cases and two postnatal cases were also admitted to the home. Thirty-two babies born in the home were not entirely breast-fed while in the institution; nine because the mother was returning to work, two because the milk was unsuitable, and 12 because there was insufficient secretion of milk. Of the 17 stillbirths in the home two were due to breech delivery and three to placenta prævia. The attendance at all the centres and clinics is increasing, and more centres and more sessions are needed in order to do justice to the work. Dr. Smith complains of the pollution of the rivers by houseboats and by lazy people throwing in refuse, making the water impossible for bathing purposes. The veterinary surgeon began his inspection of the milch cows on Nov. 1st, and in two months found two tuberculous udders among 90 cows.

A block of ten cubicles is to be provided at the isolation hospital, and will greatly increase its efficiency for dealing with a larger variety of diseases and with mixed infections. There were 17 cases of encephalitis lethargica during the year with five deaths, and eight cases of anterior poliomyelitis with two deaths.

Eastbourne.

Dr. W. G. Willoughby tells us that the infant mortality-rate was the lowest of any of the large towns of the country with the exception of some London suburbs, and that the hours of bright sunshine (1659·1) were the eighth highest recorded for the United Kingdom. The most welcome feature of the year was a larger addition to the housing accommodation. There are still a number of families lacking proper accommodation—the number is estimated at 472—but at the end of 1926 there were 254 houses in course of construction or planned, leaving a deficiency of 218. A house-to-house inquiry now in progress will verify the last-named figures. The army huts, which were occupied in May, 1919, are being gradually closed. Originally there were 188 tenements, but at the close of 1926 only 70 were occupied. The maternity home dealt with more cases than in any previous year. There were 189 confinements and 191 children born, of whom four died and eight were stillborn. There were two maternal deaths; one patient was admitted moribund from puerperal eclampsia and the other died of peritonitis after Cæsarean section. Five of the infants were not entirely breast-fed, one owing to insufficient milk and another owing to blood in the milk secreted. In one case the mother had chronic nephritis, in another phthisis, and the fifth infant was going to a foster-mother. The antenatal clinic at the home was attended by 198 expectant mothers, and the other antenatal clinic by 17 (total 215, the births for the year being 727). The six deaths from childbirth were due to puerperal fever, eclampsia, perinephric abscess, peritonitis after operation, and embolism (2). The one day-nursery in the borough was permanently closed in March, 1926. The only patient with verified encephalitis lethargica died; the only patient with acute poliomyelitis, an infant of 39 days, recovered.

Colchester.

Dr. W. F. Corfield says that an unsuccessful endeavour has been made to secure accommodation for maternity cases by taking a building from the guardians, to which separate access could have been made. Negotiations are now in progress to obtain this accommodation through the District Nursing Association. An arrangement has been made for infants suffering from a crippling defect to be attended by the specialist at the orthopædic clinic of the education committee. During the year four cases of rickets, four of congenital deformities, and one of paralysis were so treated. The schemes for the conversion of privies and pail-closets, for the provision of a water-supply for hand-flushed closets, and for the

substitution of sanitary bins for ash-pits continue to make progress. 266 houses were erected with State assistance, 98 being municipal. The housing position is getting a little easier, and notices of houses to let are beginning to appear. For the last three years the nurses at the isolation hospital have been immunised against diphtheria and there have been no cases of the disease among them. During the year the patients and staff of the Royal Eastern Counties Institution for the Mentally Defective were immunised. The "positive" patients dealt with numbered 248 out of 1037, and the "positive" members of the staff numbered 47. No bad arms followed the tests, and only three persons had a moderately severe reaction. Dr. Corfield complains that infectious cases received into the Essex County hospital from outside districts and notified from there are counted as Colchester cases. All of the five cases of encephalitis lethargica and 11 of the 58 notifications of pneumonia were of this description.

REPORTS OF SCHOOL MEDICAL OFFICERS.

Name of district.	No. on roll.	Average elementary school attendance.	No. of routine children examined.	No. of special examinations and re-inspections.	Percentage of children found on routine examination requiring treatment.†

Edmonton.

Dr. H. W. Harding describes the increase in facilities for treatment at Edmonton during 1926 and wonders if a time will come when there will be nothing fresh to chronicle. Later in the report he indicates that future preventive and curative measures will be directed towards the pre-school child. The new orthopædic clinic was opened in March and the massage and remedial clinic in April. Treatment of otorrhœa by ionisation is now employed and a class for stammerers has been started. Attention is called to the need for drying-rooms for wet boots and clothes and for the supply of slippers; the lack of them causes much invalidity among school-children. In spite of the trade depression of 1926 the condition of the children compared favourably with that of the previous year. Although there is no special school for cripples, the exceptional children are well provided for; a special class is held for partially blind and myopic; the deaf and dumb are sent by tram to a special school at Tottenham, and the feeble-minded attend the special school under the joint committee of Enfield and Edmonton. Dr. Harding argues that special day schools for mentally defective children should be abolished and special classes should be started in the elementary schools for dull and backward, borderline, and feeble-minded children. Much can be said for the establishment of classes for the dull and backward in the ordinary schools, but mental defectives often become the butt of their normal fellows, and recognising their inferiority they sometimes react by antisocial behaviour, and many children who show early antisocial signs will develop into self-helping amenable citizens when put to work which they can do and which interests them. To exclude these children from school, notifying them to the authority under the Mental Deficiency Act, is merely to shift responsibility often to the detriment of the child since institutional accommodation is quite inadequate.

Norfolk.

Coördination of the various health activities is now well established, and during the year many alterations of, and additions to, the schools have been effected. The difficulty of providing efficient trea ment in a large scattered area is well met in Norfo by six clinics in the larger villages, their work bei supplemented by the issue of vouchers for attendan by approved practitioners and consultants and l arrangements with some of the local hospital Cases requiring to be nursed are attended by th local nurse and after-care is given by voluntar workers. Motor vans are used as mobile dent clinics. Physical training is now part of the routi in all schools, and it is reported that all children tak part in the organised games and exercises. Th orthopædic scheme is now maturing, and Mr. M. V Bulman has been appointed part-time orthopæd surgeon. The close coöperation existing between th school medical service and practitioners in Norfo is shown by the record of 49 cases of parenchymato goitre treated by thyroid medication under the joi supervision of the school medical officer and loc practitioners. This is excellent, for success preventive and curative measures depends on th interest and active assistance of all medical me Dr. J. T. C. Nash, the school medical officer, associat the decrease in the mortality from tuberculosis wi the rising standard of national nutrition, and advocat the giving of milk to selected under-nourished scho children.

Colchester.

Dr. W. F. Corfield reports that although the are no blind children, there are 15 partially blin for whom there is a special class. Educable ment defectives are adequately provided for in a day scho and in a residential school forming part of the Roy Eastern Counties Institution. There are 31 ineducal children, of whom 11 are in the Royal Eastern Counti Institution, whilst the rest live at home. Dr. Corfie deplores the lack of accommodation for them; many cases it means, he says, that one of the parer is tied to the house and sometimes younger childr are scared or imitate the bad habits of the defecti The occupation centre is often a partial solution the difficulty of dealing with imbeciles. On the futu of the ex-pupils of the special school for men defectives a candid—almost a pessimistic—report given, showing that only 17 out of 61 are at wo The figures are thought to suggest that the standa of intelligence for admission to the school is on t low side. There is no open-air school in the borou nor a school for cripples, of whom 85 are mention but the list includes defects such as cleft-palate a facial paralysis. The report of the organiser physical training is included in the annual repo and we should like to see this generally done.

MENTAL HOSPITAL REPORTS.

THE *Cheshire County Hospital* at Macclesfield h 1311 patients on its books at the end of last ye 21 in excess of the normal accommodation, so t the question of providing more room has already beco acute. The shortage is on the male side. Of the 2 admissions during the year, 101 were classed as ho less. Nevertheless, there was a recovery-rate 28·1 per cent., well above the average for the previ quarter century, and the death-rate was also one the lowest on record—6·1 per cent. Post-mort examinations were made on nearly 90 per cent. the fatal cases. Four of the deaths were due typhoid fever, which attacked 32 patients. It aro apparently, through the infection of a nurse by old typhoid carrier, whose habits were very dir Water from the villa in which the nurse was lying was drunk by patients on the cricket field, and infection was spread further by old alumini utensils which had got too battered to be readily k clean. The water-supply was, of course, investiga thoroughly, and a defective tank was found and right. Further alterations are desirable, the super tendent thinks, to put the whole supply abo suspicion. Otherwise the general health was go A "Vitaglass" hammock has been erected a

hers are to be supplied; many patients have been eated by ultra-violet rays. Some nurses volunteered r an experiment on the part played by cool air in ght therapy. Those who had exposure to light gained weight, and there was an increase in blood pressure d in the leucocyte count and colour-index. Those o had cool air treatment only did not show these anges; indeed, the leucocytes were diminished, ile the red cells increased. Both sets, however, perienced tonic effects, increase of appetite and ep, and a slight increase in basal metabolism. nall rooms are to be set apart as clinical rooms; b wards and open-door wards are in practice, and ny patients have full parole or parole within the unds. Out of eight cases of general paralysis ated with malaria, four were subsequently scharged and continue well. Two others proved considerably. Hyoscine treatment for post-cephalitic cases is the subject of a special note; e results were not very gratifying. Other research rk carried on includes an investigation into the ychological origin of schizophrenia, manic-depressive ychosis, and paranoia; a great deal of routine d blood culture work has been done in the laboratory. In the occupation department 64 women were ght handicrafts and 16 men were employed in sh-making, in upholstery, and in boot-repairing. elve nurses and three attendants obtained their loma and 26 more passed the preliminary examination of the Medico-Psychological Association. This ngs the total of certificated female nurses up to per cent., a figure which the superintendent lieves to be a record. A nurses' lecture-room has n equipped with models, lantern, and epidiascope. is gratifying to learn that the standard of probaners continues to improve. New tennis and lminton courts have been made.

The *County and City of Worcester Mental Hospital* Powick houses 1129 patients and has about 130 ancies. The recovery-rate for the year was 21 per cent., and the death-rate 6·4 per cent., h an autopsy percentage of 56·2. The general lth was good, except for three cases of enteric, origin of which was not traced. Plans have been proved for the erection of a verandah for male erculous patients; this will be a great advantage, at the present these men have to be nursed in the rmary ward. A dentist has been appointed to t the hospital fortnightly, and a small laboratory been fitted up. The lack of electric current makes impossible to employ certain modern aids to itutional work—a cinematograph, kitchen devices, l so on. The farm showed a profit last year of rly £700.

The *Middlesbrough Borough Mental Hospital* houses patients, an increase of 24. The recovery-rate 39·6 per cent. and the death-rate 8·7 per cent. ty-six per cent. of the patients were kept usefully ployed, and day or week-end leave and parole e granted wherever possible. The general health 926 was good. There were only half a dozen cases tuberculosis. Operations for hernia and pyloric cture were performed by the visiting surgeons. Visiting Commissioner, remarking that "there manifest desire here to progress on modern lines," es the excellent arrangements for electrical and ght" treatment, and urges provision for separate tment of recent and presumably recoverable es, and of out-patient treatment. He comments the fact that 77 per cent. of the direct admissions e from the Poor-law institution instead of straight n their homes, suggesting that this means of ification is too often resorted to. Seventeen male ndants and two nurses are certificated and ave passed their preliminary examination.

MENTAL DEFECTIVES.

The *Royal Eastern Counties Institution* for the tally defective at Colchester issues its sixty-eighth ual report for 1926, illustrated by excellent photographs of the buildings, games, and theatrical groups. The accommodation for 1120 patients is nearly all occupied, and there is urgent need for extension. Plans have been approved for some enlargement, but progress is slow. The general health and nutrition was good and there were only four cases of tuberculosis. Day service and living-in service have been continued, the chief development during the year was the increasing use of foster-mothers for quiet, well-behaved cases. The children go out on long leave of absence; this is preferable to putting them out under guardianship, because if anything happens, either to patient or foster-mother, the former can be brought back to the institution at a moment's notice. The medical superintendent finds from experience that, for the great majority of defectives, life in an institution is happier and more successful than any other scheme. Daily service is better, too, than boarding-out. Once a beginning of liberty is made, the defective generally thinks all restrictions are gone, and parents or employers will not enforce the terms of licence. The superintendent confesses to a considerable degree of pessimism about the possibility of getting the higher-grade cases back into the world. The only high-grade cases that ever come into an institution are those which have failed many times to adapt to an outside environment, and will fail again. The only class he sends out without misgiving is the quiet, well-behaved medium grade who is mentally a child and content to live for always as a child, under a good foster-mother. The school girl guide company had a fortnight's summer camp at Langham Hall and have taken 133 second-class and proficiency badges. The scout troop came out fifth in the ambulance competition for Colchester scouts. The patients make every article of clothing, every bit of furniture, every brush, mat, or basket needed by the institution, as well as selling products outside. More orders would be welcomed, but it is gratifying to learn that the coal strike did not produce the drop in income that might have been anticipated. As diphtheria had given a good deal of trouble for some years previously, the Schick test was tried on all those whose guardians gave consent. All the positive cases were immunised and there has been no more diphtheria. There were no mishaps among all the 1084 persons dealt with. There was a mild epidemic of influenza during the year and two patients died, but the tuberculosis death-rate was only 0·81 per cent. Epileptics were treated with luminal; the conclusion was that it helped to modify the attacks while not curing the patient.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 30TH, 1927.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 185 (last week 195); scarlet fever, 1623; diphtheria, 801; enteric fever, 78; pneumonia, 562; puerperal fever, 45; puerperal pyrexia, 97; cerebro-spinal fever, 7; acute poliomyelitis, 20; acute polio-encephalitis, 1; encephalitis lethargica, 23; dysentery, 3; ophthalmia neonatorum, 93. There was no case of cholera, plague, or typhus fever notified during the week.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 25 (2) from measles, 9 (1) from scarlet fever, 12 (1) from whooping-cough, 21 (4) from diphtheria, 68 (8) from diarrhœa and enteritis under two years, and 15 (2) from influenza. The figures in parentheses are those for London itself.

Registration of Stillbirths.—Under the Birth and Death Registration Act, 1926, which came into force on July 1st last, 980 stillbirths were registered up to the 30th of the month in the great towns of England and Wales, including 171 registered in London, giving a weekly average of 229 and 40 respectively.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

SCOTTISH BOARD OF HEALTH.

ON Thursday, July 21st, the House went into Committee of Supply on the Civil Service Estimates for 1927, Captain FITZROY, Deputy Chairman of Committees, in the chair.

Housing Conditions in Scotland.

On a vote of £2,387,155 for the salaries and expenses of the Scottish Board of Health,

Mr. MACPHERSON said he had read with pain that part of the report of the Scottish Board of Health which referred to housing conditions in Glasgow. He had never read a more pathetic or terrible description of housing conditions than was contained in that report. It had aroused great feeling in Scotland, and he would be glad to hear from the Secretary of State for Scotland that something was being done to remedy conditions which were a disgrace to the twentieth century. The condition of rural housing in Scotland was also a very serious one. It was not so much that new houses were needed—though that was a very essential thing—as that they needed the old houses to be repaired. He thought that the Secretary of State for Scotland should take every step in his power to explain to local authorities what powers they had under the new Act which was recently passed. He would like also to refer to the part of the report which dealt with the special Highlands and Islands Medical Service Fund. During the passing of the Insurance Act there was a provision made for the special conditions in the Highlands and Islands of Scotland, and it was right to state that the Scottish Board of Health had been very active with regard to that part of the country. A great deal of good had been done, and the fund generally had been of very great assistance in those remote parts. The fund was still at the pre-war figure of £42,000, and the Board of Health did not think that they would be able to cope with any new scheme unless and until there was a reconstitution of the fund. They confessed quite openly on page 180 of the report as follows :—

"In the meantime, until the fund is reconstituted, the assistance granted from it must be restricted to the services already in being, notwithstanding that the time seems ripe for a scheme of development in the Highlands and Islands and for the introduction of a system of specialised services, for both of which there is great need in this part of the country."

He need not tell the Committee how essential it was to have a first-class local hospital in the various parts of Scotland. At the present time they had at Dingwall the Royal Memorial Hospital, and they were busy rebuilding and extending one of the finest institutions in the country—the infirmary at Inverness. He did not know whether the Board of Health had taken, so far, any interest in these hospitals ; though he believed they had realised the importance of having efficient local hospitals in the various parts of Scotland. They also wisely recognised that it was necessary to have specialised services. Nobody knew what a hero the ordinary Highland doctor was. In the wildest storm, over bad roads, sometimes over arms of the sea, he went at all hours of the day and night, very often for a miserable fee, to attend to the poorest people in the land, and he, for one, would be glad to see any betterment of the conditions of the Highland doctor's service. It was far too much to expect a single individual to be responsible for the welfare and the health of an entire community without some such assistance as could be given to him from a hospital as nearly situated to his work as possible. He would ask the Secretary of State for Scotland if his attention had been drawn to the appeal made by the medical officers for the consideration of the establishment of a superannuation fund. They regarded themselves now as being in the State service, and judging from the report which he had just been reading it was quite clear that they had some claim to be considered. There was another important point. It was often very difficult for the local doctor to get a suitable house. The local doctor should be guaranteed a house, or the site for a house, in the remote parts where it was often difficult to get them. He was glad to see in any case that the Board of Health were still considering that point. Last year he thought they had caused the erection of three houses for doctors in various parts of the country. That was the sort of thing that was worth doing.

Overcrowding and Disease.

Mr. J. STEWART said there were in Glasgow 277,000 people living in overcrowded conditions. Overcrowding in Scotland was three persons per room, while in England it was only two persons per room. In a single apartment they ranged from four per room to as many as 12 per room, and in the room and kitchen houses they ranged from six and seven to over 12 per house. That must produce results which were inimical to the welfare of the country, and it did r result in the saving of money. They were spending mor very freely everywhere throughout Scotland in furt extension of sanatoria and hospitals to deal with dise In a district of Glasgow where he spent his early days per 1000 of the children born died before they reac one year of age. Yet the standard rate for Glasgow was per 1000. The diseases were respiratory diseases, tuber losis in its various forms, measles, and whooping-cou The children were dying practically like flies. Thousa of children were continuously pouring in and out of infectious diseases hospitals as a result of bad hous conditions. Every child cost well over £1 per week, and cases of tuberculosis about £2 per week. After they w cured they were sent back to the conditions under wh they had contracted those diseases. According to medical officer of Paisley rickets was a consequence of pove and bad environment. Even in the new houses the peo who had just come from the slums to the extent of 28 cent. were living under overcrowded conditions. charge against the Government was that they had insisted upon a better standard of housing. It might true that local authorities were supine, or even hostile an improved standard of housing, but he had yet to le that the authority of the Scottish Board of Health was limited that they could not deal with recalcitrant l authorities. The people from the slums who had g into the new houses were carrying verminous conditi with them. So far as Glasgow was concerned, the prob grew worse and worse. When they investigated it in 1 they discovered that 57,000 houses were required im diately. To-day the number required was 107,000 hou The number of insanitary houses, according to the figure 1909 and 1910, was 13,000. To-day, in spite of s clearances, that number had risen to 20,000. The med officers of the local authority pointed out these things, nobody was concerned about altering the conditions. was a mistake to think that this country could survive v a poverty-stricken population pulled down through housing into a bad state of health, and growing up stu and dwarfed.

Reply of the Under Secretary of State for Scotland.

Major ELLIOTT, replying to the debate, said that t depression had been affecting Scotland for several ye But if they tested the matter by statistics they found there had been an increase in the health of the pe a steady fall in sickness, and an improvement in nearly the great questions affected by the administration of Scotl They had been able to maintain their past standard e in the stress of deep industrial depression, and how they might desire that things should be better they n recognise that they had made some progress. He w like to give some figures dealing with tuberculosis. 1926 the ordinary death-rate per 100,000 of the popula in non-pulmonary cases fell. It was 34 in 1925, and 3 1926. The death-rate per 100,000 of the population f all forms of tuberculosis fell from 110 in 1925 to 99 in 1 Compared with 1916, there were 1744 fewer people who from non-pulmonary tuberculosis ; making a total of fewer deaths from tuberculosis in 1926 compared with 1 The number of beds definitely reserved for the treatm of tuberculosis was steadily rising, and they now had beds as compared with 4170 at the end of 1925, an incr of 169 beds. The provision of tuberculosis beds was tinuing, and a number would come into use in relief of problem in the course of the next few months, or the year. As for infantile mortality, that also continue fall. The rate was 83 per 1000, or eight less than the in 1925, and nine less than the rate for the immedi preceding five years, and 13 less than the rate for preceding 10 years. It was the lowest rate on rec except that for 1923. In the report of the Board of He they had not in any way ignored the desperate and appa state of housing in many places in Scotland. It was their policy to cover up that festering sore. Unless pu opinion was continually reminded of the necessity for de with this problem there was danger that they would into a state of complacency. That was the last w however, which could be applied to the Secretary of S for Scotland in that regard. He had been untiring in efforts to forward the solution of that problem, an bring the facts to the notice of the authorities, an had taken steps of a very drastic kind on more than occasion. The figures showed that last year they had largest number of houses ever built in one year in Scotl and they were able for the first time to do something tow catching up with the arrears as well as dealing with current wastage. This year, up to the end of Jun perhaps the beginning of July, they had built the w of the year's requirements for Scotland, and every h built from now to the end of the year would be a clear and go towards the reduction of arrears. As rega rural housing, nearly all the rural local authorities a

mitted schemes, or had now got schemes in operation. Macpherson had mentioned the Highlands and Islands nd. That fund had an accumulated balance on which y were drawing to the extent of between £18,000 and ,000 a year, but by 1928 or 1929 that accumulated ance would have run out and his right hon. friend would aced with the unpopular duty of approaching the Treasury h a request for special treatment for Scotland.

Ir. T. JOHNSTON moved the reduction of the vote by £100. said that he did so in view of the unsatisfactory nature he Government's reply on the many points raised.

he motion to reduce the vote was rejected by 211 votes 96.

NURSING HOMES (REGISTRATION) BILL.

he Nursing Homes (Registration) Bill was considered by nding Committee A of the House of Commons on Tuesday, y 26th. Mr. MORGAN JONES was in the chair.

Unorthodox Practice.

iscountess ASTOR moved an amendment to Clause 1 ich deals with the registration of homes), providing—

hat where the application for registration relates to a nursing e (other than a maternity home) in which treatment by ical methods is not administered, the authority shall not se to register the applicant on account only of the conditions the home, if a new home, is not under the charge of a dent duly qualified medical practitioner or duly qualified se; that there is not a proper proportion of qualified nurses he staff; or, in the case of a nursing home which was in tence at the commencement of the Act, that it is not under superintendence of a qualified resident nurse.

urged that the amendment would carry out the policy he Minister of Health when he stated that the Ministry ld not cut themselves off from any form of treatment ch was not orthodox. Under the clause as it stood it ld not be possible for an osteopath or Christian Scientist carry on a registered nursing home unless there was a y qualified medical practitioner in charge. The amendt would give complete freedom to Christian Scientist sing homes to be run on their own lines.

ir KINGSLEY WOOD (Parliamentary Secretary to the istry of Health) said that he could not accept the endment. He had no desire to enter into a discussion o the merits of Christian Science. His only desire was ee that the Bill reached the Statute Book in a proper n. The conditions for registration already laid down in clause were very proper conditions, and if the amendment e accepted it would be possible to drive a coach and through the whole of the Bill. Clause 6, however, bled a supervising authority to exempt hospitals, or ilar institutions, which were not carried on for profit. re might be some possibility—he did not know—of an lication being made under that clause by one of the es which Lady Astor had in mind.

iss SUSAN LAWRENCE said that she was strongly against amendment, which, in her view, would make the Bill, ch was already a weak one, quite ridiculous. What was use of a nursing home if no medical treatment was given t?

iscountess ASTOR said that thousands of people had efited from Christian Science nursing homes, but the se would prevent people from getting treatment which y wished to have from unqualified people. In Canada the United States this was a recognised form of treatt, and it was growing in this country.

Ir. CHAMBERLAIN (Minister of Health) said that he failed see what connexion Christian Science had with the endment. If the amendment were carried it would allow sorts of practice to be included within the scope of the , quite apart from Christian Science. Any kind of rthodox practice would be possible under the cloak of amendment, and the local authority would be unable to se registration to homes which were carried on without roperly qualified staff. The Ministry did not want to rive the country of opportunities of healing by anyone ong as those who sought treatment by those methods e perfectly cognisant of the risks which they were ning. But under this Bill they were entrusting the local ervising authority with the power to register nursing es, and such authorities would not be able to avoid t responsibility by reason of an amendment of this nature. would still be open to the local authority to refuse stration on other grounds which were provided in the se.

Ir. J. BAKER said that this seemed to be a backward and a forward step. He was not going to argue that the ical profession in this country was the best on earth, the amendment raised rather too big a question to be led in committee.

iscountess ASTOR said that the Minister of Health had that he did not object to Christian Science, but did the t hon. gentleman realise that under the Bill if Christian ntists wanted to set up a nursing home they could not o?

Sir D. NEWTON: They can do so if there is a medical man in the home.

Viscountess ASTOR: But no one wants a medical man. Continuing, the noble lady said that this was a very serious matter, because they were going to put Christian Scientists into the category of quacks, herbalists, and bone-setters. Hon. Members might laugh, but more and more there would be a demand for Christian Science homes.

Mr. BARKER said he had no knowledge of Christian Science, but he thought that the Committee should be very careful or they would enter into a sort of religious persecution. They ought not to force on people medical treatment in which they did not believe.

Dr. VERNON DAVIES said that they were not concerned with religion or Christian Science. He would remind Lady Astor that Christian Scientists recognised the need for medical treatment in such cases as a broken leg or infectious disease. But these Christian Science homes regarded themselves as the equal of the best nursing homes in the district and charged similar fees. They were therefore a commercial proposition under the ægis, if they liked, of the Christian Science religion. He urged that the Committee had no right to give exemption to such institutions.

Miss SUSAN LAWRENCE said that there was no class more preyed upon than the sick poor. They could see the absurd treatments which were advertised in the newspapers. This amendment would permit every sort of quackery in the world.

Mrs. HILTON PHILIPSON said that she was quite in sympathy with Lady Astor. She thought that the Christian Scientists did an immense amount of good, but the amendment was far too wide, and she would certainly vote against it.

The amendment was negatived without a division.

Amendments Carried.

Mr. GERALD HURST moved an amendment to put a time-limit on the privileges to be enjoyed by those nursing homes which were in existence at the passing of the Act. He said that they did not want a privileged class of nursing homes to be continued in perpetuity.

Sir K. WOOD accepted the amendment, which was agreed to.

Dr. VERNON DAVIES moved an amendment to Clause 4 (by-laws) to provide that if a local authority thought that miscarriages were too frequent at a particular home they might keep an eye on that home and see that the miscarriages were really genuine.

Sir K. WOOD accepted the amendment, which was agreed to.

Information as to the Cause of Deaths.

Sir R. LUCE moved an amendment to leave out of paragraph (*b*) of Clause 4 the reference to the making of a by-law requiring a statement of the cause of a death in a nursing home. He said that these words occurred in the Midwives and Maternity Homes Act, but since that Act was passed last year another Act had been passed altering the law in regard to the registration of births and deaths, and one of the clauses of that Act provided that the cause of death should be a confidential matter between the medical man who attended the patient and the registrar, and if these words were left in the Bill it would be the duty of whoever was running a home to state the cause of death, which she ought not to be in a position to do.

Miss LAWRENCE said that she opposed the amendment. They were dealing with deaths of children, and possibly mothers. This was a matter in regard to which there were sometimes suspicions of malpractices, and she would be very sorry to see the law relaxed.

Sir K. WOOD said that he agreed with Miss Lawrence that they must exercise care in regard to this matter. He had consulted the Registrar-General, and he would see that in every case where there was likely to be any suspicion information was sent to the local supervising authority.

Lieut.-Colonel FREMANTLE said that he was not at all satisfied with Sir K. Wood's explanation.

Sir K. WOOD said that he would endeavour to make arrangements by which the Registrar-General would inform the local supervisory authority of the number of deaths which might occur in a particular home, and if they appeared to be abnormal the authority would be placed on its guard and would be able to send an inspector to see what exactly was going on.

Sir R. LUCE said that it was not the object of the amendment to hide anything. What was desired was to make sure that unauthorised persons were not able to give the cause of death.

Dr. VERNON DAVIES suggested that the local supervising authority should be given the power to ask the Registrar to see the cause of death in any case in which they had a suspicion that there had been any irregularity.

Sir K. WOOD said that obviously he would have to have a further interview with the Registrar-General and would convey to him the wishes of the Committee.

The amendment was agreed to.

Inspection.

Sir R. LUCE moved an amendment to Clause 5 (inspection of nursing homes), designed to make it clear that while the medical officer of health was the officer normally responsible for the inspection of nursing homes the local supervising authority could in certain cases direct other officers to carry out that duty.

The amendment was agreed to.

The Non-County Borough as Supervising Authority.

Sir D. NEWTON moved an amendment to Clause 8 (local supervising authority), providing that the powers of the local supervising authority should be vested in the non-county boroughs as well as in the county councils and county boroughs. He said that many non-county boroughs had a skilled staff of medical officers, sanitary inspectors, and whole-time health officers, and were fully able to carry out the duties.

Lieut.-Colonel FREMANTLE thought that this amendment would lead to duplication of inspection. It would open the door to a lot of abuse. He suggested that a fair compromise would be attained if they inserted the following words :—

"Where the council of any borough or urban district, of which the medical officer of health is precluded from engaging in private practice, shall resolve that the powers of a local supervising authority under this Act would be more efficiently administered by them without detriment to the administration of the Midwives Acts, the county council may by resolution delegate such powers to that council; and that council shall thereby become the local supervising authority under this Act."

Sir K. WOOD said that he thought that they were entitled to say that those authorities which had whole-time medical officers of health should be entrusted with the supervision of nursing homes.

Sir D. NEWTON'S amendment was carried.

Definition of a "Qualified Nurse."

Sir R. LUCE moved an amendment to Clause 9 (interpretation), providing that—

In relation to any premises used and intended to be used solely for the reception of, and the provision of nursing for, a class of patients in whose case the requisite nursing could be suitably and adequately provided by nurses of a class whose names were contained in some part of the register of nurses required to be kept under the Nurses Registration Act, 1919, other than the general part of that register, references in the definition of "qualified nurse" contained in subsection (1) of this section to the general part of the register shall be construed as including references to that other part of the register.

He said that the object of the amendment was to provide that where a home was devoted to one particular class of patient that those in charge of it should be able to employ nurses who had been trained in that particular branch of treatment.

The amendment was agreed to.

A New Clause Applying to London.

Mr. GERALD HURST moved the following new clause applying the Bill to London :—

This Act shall apply to the administrative county of London subject to the following modifications: (i) As respects the county of London the London County Council and as respects the city of London the Common Council shall be the local supervising authority; (ii) any expenses incurred under this Act by the London County Council shall be defrayed as general county expenses and any expenses so incurred by the Common Council shall be defrayed out of the general rate; (iii) the London County Council may delegate to the council of any metropolitan borough all or any of its powers under this Act other than the power to make by-laws, and any such delegation may be either absolute or subject to such terms or conditions as the London County Council may think fit, including conditions for the repayment by the London County Council to a council to whom powers are so delegated of the whole or part of the expenses incurred by that council in the execution of the powers so delegated; (iv) any expenses incurred by the council of a metropolitan borough in the execution of any powers delegated to it shall, in so far as those expenses are not repaid to that council by the London County Council, be defrayed as part of the general expenses of the council, and any fees received under this Act by the council of a metropolitan borough shall be paid into the fund out of which expenses incurred under this Act by that council are to be defrayed.

The clause was agreed to.

The Committee stage was completed and the Bill was reported to the House.

HOUSE OF COMMONS.

THURSDAY, JULY 28TH.

Approved Societies and Dental Treatment.

Mr. HAYES asked the Minister of Health whether he was aware that when a member of the National Health Insurance submitted an estimate for dental treatment which included the administration of a general anæsthetic, the National Amalgamated Approved Society questioned the dentist upon this treatment and demanded to be advised why the extraction could not be made under a local anæsthet and whether, in the interest of the patients, he would reco mend to approved societies the desirability of discontinui the practice of questioning professional treatment. Mr. CHAMBERLAIN replied: I am not aware of the pract of the particular society referred to in the first part of t question, but I understand that the Dental Benefit Jo Committee, by whom the scale of fees and conditions service were negotiated, have at present under conside tion the question of the right of a patient to choose t anæsthetic to be used in his case. Pending the committe decision, I do not propose to take any steps in the matter.

Effects of Insulin Treatment.

Mr. FORREST asked the Minister of Health how ma people suffering from diabetes had been cured by the tre ment of insulin; and in how many cases such treatme had merely controlled the disease but not cured it.—M CHAMBERLAIN replied: Insulin is not a curative ag in the ordinary sense of that term, and it is administe with the object of neutralising for the time being the con quences of the disease, although in certain cases its prolong administration may be followed by a diminution in, even the entire disappearance of, the active symptor No statistics are available as to the number of persons w have received this treatment nor is it possible to ascert the number of cases in which the administration of insu has contributed to the cure of this disease.

FRIDAY, JULY 29TH.

Diphtheria in Dagenham.

Mr. BROAD asked the Minister of Health the number cases of diphtheria in Dagenham during the last 12 mont and the number of fatal cases; whether this disease v prevalent throughout Essex; and whether any and, if what special steps were being taken to combat it.—M CHAMBERLAIN replied: The numbers of cases of, and dea from, diphtheria in the urban district of Dagenham have b as follows :—

	Cases.	Deaths
In 12 months ended July 2nd, 1927 ..	80	9
In 3 weeks ended July 23rd, 1927 ..	23	4

I am advised that there is no exceptional prevalence the disease throughout Essex, although a small outbr recently occurred in Dagenham. I am informed that usual precautions were taken, including the removal of the cases to hospital.

Importation of Cocaine and Cocaine Hydrochloride.

Mr. FENBY asked the President of the Board of Tr if he was aware that the exemption orders applied for year under Section 10 (5) of the Finance Act, 1926, in resp of cocaine and cocaine hydrochloride, being prod liable to duty under Part I. of the Safeguarding of Indust Act, 1921, had not yet been issued; that his departm were refusing to issue these exemption orders, altho the products in question were still not made in His Majes dominions; and that, in consequence, hospitals and general medical service, who were the chief consumer these products, which had to be imported, were compe to pay considerably more than would otherwise be the would he take steps to issue the exemption orders in ques forthwith; and, if not, what further period of time proposed to allow in respect of the products in quest —Sir P. CUNLIFFE-LISTER replied: Before I can make recommendation to the Treasury under Section 10 (5) of Finance Act, 1926, to exempt any article from duty, I m be satisfied that there is no reasonable probability that article will be made in His Majesty's dominions in s stantial quantities within a reasonable period. Preparat for the manufacture of these materials in this country well advanced, and I do not propose to make any rec mendations to the Treasury on the subject at present.

Male and Female Population of Scotland.

Dr. SHIELS asked the Secretary of State for Scotl the male and female population of Scotland for 1913, 1 and 1921 to 1927.—Sir JOHN GILMOUR replied: By Census of Scotland taken in 1921 the male population found to amount to 2,347,642 and the female popula to 2,534,855. Estimates by the Registrar-General Scotland of the male and female populations in the o years referred to in the question are shown in the follo table :—

Year.	Male.	Female.	Year.	Male.	Fema
1913	2,296,370	2,431,762	1924	2,347,228	2,534,
1919	2,313,600	2,506,477	1925	2,352,708	2,540,
1922	2,358,201	2,546,255	1926	2,354,441	2,542,
1923	2,356,587	2,544,513	1927	2,353,500	2,541,

"Audi alteram partem."

THE SUPER-EGO OF FREUD.

To the Editor of THE LANCET.

R,—The tendency to postulate a living and lligent agency as the cause of phenomena not iediately identifiable with familiar responses to ronmental forces would seem to be an innate acteristic of cerebral protoplasm. The snake that wandered out of the bush on to the sea-shore es at the rolling waters, the dog growls and erects dorsal hair at the moving newspaper, the oceros charges the railway train, the horse shies ts shadow, and man invents hosts of demons, es, ghosts, monitors, and psyches to account, he one hand, for those several feelings, fears, ies, and dreams that are in reality but sensory bral cell disturbances set up by afferent impulses nating from enteroceptive, proprioceptive, and roceptive sources, and initiated therein, directly ndirectly, by environmental stimuli, and on the r hand, for those several behaviours that are but motor reactions of the organism to such afferent ulses. In lower animals such characteristic, essing obvious survival value, is a vital necessity, rimitive man an excusable frailty, in civilised a regrettable backsliding. Just as the liar, scape detection, is often driven, like the ancient ts piling Ossa on Pelion, to cover one lie with her, so those who invent an absurdity in explana- of a phenomenon not altogether understood, find themselves in the unenviable position of ng to invent yet more fantastic absurdities to er up their illegitimate first-begotten one. ent cosmologists, observing that objects fell ss supported, accounted for the earth's apparent ility by the assumption that it rested on the of an elephant. It was a cleverly thought-out cing hypothesis, for such otherwise mysterious ts as thunder and earthquakes were easily ex- ed away, as the shaking and trumpeting of the ic pachyderm. But embarrassing questions began e raised concerning the foothold of the elephant. little difficulty was overcome by recourse to a sal tortoise on whose back the elephant with his dane burden was placed. When, in due course, ar information was requested concerning the ise, the wily sages resorted to the device of muting that creature into a pelagic turtle which set swimming about in an infinite sea, thus tively silencing the hecklers.

e habit of alluding to the mind as though it were mething standing apart from brain is common ngst those who have never seen the inside of a an skull. Unhappily, even medical men are not ether innocent of the fault of applying such tion-begging epithets as "elusive entity" either he mind itself or to what is equatable with it. ude to such expressions as, for instance, "ego," f," "personality," "psyche," &c., which, while ittedly convenient counters of thought in ordinary y-day parlance, should have no place in a strictly itific terminology, seeing that they introduce uncalled-for difficulties and obscurities. Even Haldane, whom his worst enemy could not accuse aterialistic leanings, laughs to scorn all attempts ucidate the meaning of "self." You will never this "*supposed* individual," he says in his Gifford res, for the simple reason that "it is an abstrac- ic" which you "have been trying to identify reality." And as for the "ego," he whittles ay until nothing is left; it is, he says, "a mere nptotic regress towards a notional pure subject knowledge—a thinker without thoughts, an raction, nothing at all." [1]

The "ego" or "self" is, I submit, nothing more nor less than the living body plus a functioning or functionable brain. Our ideas of personality are framed in the somewhat deceptive setting of memory and behaviour. Just as the woodsman who, though he has frequently renewed during the long years of use both haft and blade of his axe until nought of the original implement remains, still continues affectionately to allude to it as "my old axe," so we, equally unwarrantably, confer upon our ever-changing organism a personality extended and immutable in time. We are deceived by the quiet and exquisitely accurate manner in which the atoms that come fit into the niches, so to speak, and carry on with the work of the atoms that go.

Not content with having called into existence a primary cerebral monitor, a fell demon of the unconscious that haunts the cavernous recesses of our brains, and holds the keys of the casket in which are locked our most secret and sacred thoughts, holds them, too, in a grasp that only "analysis" can relax; not content with having housed within us a horrid imp that is ever inciting us to deeds unmentionable (a kind of, to anti-paraphrase Arnold, something-not-ourselves-that-makes-for-unrighteousness), Prof. Freud has now hatched out of the "father-complex" yet another monstrosity which he has christened the "super-ego" who, apparently, stands minatorially over the common or garden "ego." [2] One wonders where it will all stop. At this rate "egos" will have to be distinctively labelled, like the units of star systems, with prefixes, alpha, beta, gamma, &c., or, like pieces of ordnance, with suffixes, Mark 1, 2, 3, &c., or, *horribile dictu*, when they run into the centuries, with numerals after the fashion of the salvarsans and their congeners! But why not save trouble and classify them like other troublesome entities in a simple but comprehensive statement that "Little Egos have Super-Egos whose function 'tis to right 'em. And Super-Egos have higher Egos, and so *ad infinitum*."

I am, Sir, yours faithfully,

CHARLES M. BEADNELL,
Cwmgoedwig, Llanfarian. Surgeon Rear Admiral, R.N.

CORONARY THROMBOSIS.

To the Editor of THE LANCET.

SIR,—Dr. L. Abrahamson, in his interesting account in THE LANCET of July 30th (p. 224) of a case of coronary thrombosis, takes the text-books to task for so rarely treating the condition as "an ante-mortem clinical entity." Surely, the ante-mortem importance of the condition has been recognised for years. The 1908 edition of "Osler" considers very fully the effect of a non-fatal occlusion of a coronary vessel by a thrombus or embolus—a condition of fibrous myocarditis—which "may result from the transformation of areas of anæmic necrosis." Osler, indeed, emphasised in the same place that "a knowledge of the changes produced in the myocardium by disease of the coronary vessels gives a key to the understanding of many problems of cardiac pathology."

Dr. Abrahamson, though quoting Dr. A. G. Gibson's paper,[3] hardly gives the latter sufficient credit for it. Dr. Gibson very ably sums up the symptomatology of the condition of coronary thrombosis (ischæmic necrosis) when he states that "chronic cardiac failure in old people, in the absence of syphilis, old rheumatic affections of the heart, or pernicious anæmia, is almost certainly due to ischæmic necrosis," and that "chronic cardiac failure plus evidence of aseptic embolism makes the diagnosis of ischæmic necrosis practically certain." As will be seen by these statements, therefore, coronary thrombosis must be a common condition in general practice. Dr. Abrahamson, however, does well to refer to the subject, as there is no doubt that practitioners do not

[1] ifford Lectures, 4 and 6, in Pathway to Reality, by the Hon. R. B. Haldane, F.R.S.

[2] The Ego and the Id, by Sigmund Freud. Translated by Joan Riviere. International Psycho-Analytical Library.

[3] THE LANCET, 1925, ii., 1270.

keep the thrombotic origin of heart disease sufficiently in mind.

It is my experience that coronary thrombosis is on the increase—a fact which I attribute to the increased prevalence of influenza latterly. In a recent letter[4] I drew attention to the common occurrence of pulmonary infarction in influenza, and mentioned that embolism occurred in other situations as well. Cerebral thrombosis, I have noted, occurs in old people during the influenza epidemics, and I have no doubt (by analogy) that many of the cases we general practitioners label "myocarditis following influenza" have a similar thrombotic origin in the coronary vessels.

I have seen several cases since the beginning of 1926. One man of 67, who had a "severe cold" in February, 1926, presented the identical picture described by Dr. Abrahamson in his case, with this addition—there was a marked pericardial rub. I expected the man to die; he is still alive, but his heart is badly scarred, and I would not be surprised to see him dropping dead at any time. On Jan. 3rd, 1926, I saw a very fat women over 60, with an acute præcordial pain and an ashy colour and imperceptible pulse, and could only diagnose coronary embolism; the patient recovered. It was curious that I saw an endocarditis case with a pulmonary infarct on Dec. 29th, 1925, and another endocarditis case with hæmaturia (renal infarction) on Dec. 31st, I saw also many embolic cases right up to May, 1926. There is no need to state that influenza was very prevalent during this period. On May 14th and 16th of this year I had two sudden deaths—both very suggestive of coronary embolism. On May 10th I saw a case of pulmonary infarction. And so on.

It is my belief that coronary thrombosis or embolism may occur in healthy people as the result of an attack of influenza, though, of course, it is more likely to occur in the subjects of arteriosclerosis. It is interesting to note that the youngest case described by Dr. Gibson—a woman of 25—followed influenza; and that there was a history of influenza in two of the three cases described by Dr. Carey Coombs, though the latter put inverted commas to the diagnosis of influenza.

It is probable that coronary thrombosis may result as the effect of any of the infectious diseases in the same way. But owing to influenza being so constantly with us I cannot help thinking that it must take first place nowadays.

I am, Sir, yours faithfully,

AMBROSE W. OWEN.

Aberdare, Glam., August 1st, 1927.

TREATMENT OF PERNICIOUS ANÆMIA BY RAW LIVER.

To the Editor of THE LANCET.

SIR,—The report in your issue of August 6th (page 283) of a paper on this subject by Prof. Minot, of Boston, makes giving a short account of a patient now under my care perhaps worth while.

H. M., male, aged 44, was admitted into the Prince of Wales's General Hospital on May 20th last suffering from pernicious anæmia. He was very ill indeed. Free hydrochloric acid was absent from his stomach contents. His teeth were in good order. The red blood-cell count was given as 1,300,000 and the hæmoglobin as 35 per cent. Poikilocytosis, anisocytosis, polychromatophilia, punctate basophilia, seven normoblasts and four megaloblasts were reported by the pathologist (Mr. Benians). Treatment with raw calves' liver was at once instituted, the patient taking 8 oz. per day. Some was pounded and given in soup, some was lightly browned in slices so that the inside remained red; most was taken in bread and butter sandwiches. In addition, a mixture was given of dilute hydrochloric acid with tincture of perchloride of iron (40 ♏ and 20 ♏ respectively) thrice a day after food in half a pint of water. In successive weeks the red cell count rose to 2,300,000, 3,100,000, 3,900,000, and 4,220,000, the hæmoglobin increasing to 75 per cent. and giving, on June 17th (four weeks after admission), a colour-index of 0·9. On this date the only microscopical abnormality noted by the pathologist was very slight anisocytosis. Following discha from hospital on June 21st, there was a fall in the red blo cell count to 3,840,000, but the lost ground was quic regained, 4,250,000 being reported on July 7th, 4,380,000 on July 26th.

The patient looks perfectly well, is earning living as a boot repairer, and continues to take da 4 oz. of raw liver with 30 ♏ of dilute hydrochlo acid and 15 ♏ of the iron tincture after the th principal meals. It is hard to resist the conclus that the claims made for this method of treatm are well founded, and attention may be drawn the paper on the subject by Aitoff and Loewy t appeared in the *Presse Médicale* for April 30th, 19

I am, Sir, yours faithfully,

August 7th, 1927. F. G. CROOKSHANK

QUININE AND CHINOSOL SUPPOSITORIE

To the Editor of THE LANCET.

SIR,—The letter of the Hon. Sec. of the C.I Medical Research Committee in your issue of July 3 calls for a reply. In writing my previous letter only object was to contribute to the study o problem which both that Committee and my are anxious to elucidate. It is unusual to speak medical procedures being "imitated"; we desc our methods fully so that other workers may ad them and further test their efficiency.

It is of minor importance who was the first "initiate discussion on the application of chin to contraceptive problems," but in view of the cl put forward by Mr. Roe the following facts be of interest. Miss Ettie Rout informs me chinosol has been in use as a contraceptive for m years, that it was used both in the form of a gr ointment and in greasy suppositories during later years of the war, and that in 1921 a chem manufacturer in London, at her request, made gr suppositories and non-greasy effervescing tal containing one-fifth of 1 per cent. of chinosol. Furt in 1921 a patient brought me from Austria t contraceptive preparations containing chino (1) cocoa-butter suppositories, (2) a greasy ointm and (3) a non-greasy jelly. In 1923 I bough Dresden greasy suppositories containing one-t of 1 per cent. of chinosol in a lanoline-cocoa-bu base, and some others of double that strength.

In the face of these facts it is difficult to ima that there can be any real novelty about the prep tion recommended by the C.B.C. Committee, un of course, there is some new and important fa about the composition or preparation of their chi suppositories which makes them essentially diffe from all previous varieties. I am sure that n others of your readers besides myself would welc the Committee's description of the exact formu the "perfected form" which they have foun satisfactory in over 800 cases.

I am, Sir, yours faithfully,

Harley-street, W., August 8th, 1927. NORMAN HAI

ASTHMA AND ARTHRITIS IN ALTERNAT

To the Editor of THE LANCET.

SIR,—The following case is, I think, some unusual.

Mrs. S——, aged 64, suffered constantly from as for many years. After a short visit to the seasi 1922 her asthma was apparently cured, but she deve rheumatoid arthritis of all the metacarpo-phala joints, with the exception of those of the middle fing both hands, which never became affected. Since the has suffered from either asthma or arthritis, never together, the attacks alternating at quite irregular inte without being influenced by either climate or drugs.

The only reference I can find to this conditi in H. W. Crowe's "Treatment of Chronic Arthr where an almost similar case is quoted as being un

I am, Sir, yours faithfully,

SYLVIA B. WIGODER, M.D. D

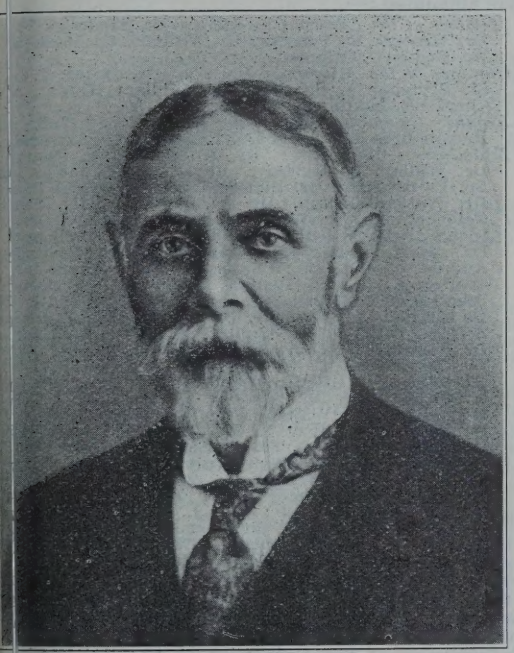
Dublin, August 2nd, 1927.

Obituary.

CHARLES WILBERFORCE DANIELS, M.B. CAMB., F.R.C.P. LOND.

ING in an age of great discoveries in tropical ine, Dr. C. W. Daniels rendered outstanding es as a teacher and an investigator. His modest retiring nature did something to prevent full nition of his merit, but the news of his death on st 6th will be received with real regret by the pupils and colleagues who came under his kindly timulating influence.

n in 1862, Charles Wilberforce Daniels was the son of the Rev. Thomas Daniels, rector of St. , Hulme. From Manchester Grammar School



DR. C. W. DANIELS.

n a scholarship at Trinity College, Cambridge, roceeding for clinical training to the London al. There he rapidly gained a reputation for ency in medicine, with a special leaning to ery, and after qualifying in 1886 he filled the of house physician, house surgeon, and resident heur. He entered the Colonial Medical Service 0 and was sent for duty to the Fiji Islands, he spent several years, and made a careful of the dysentery epidemics occurring annually sugar plantations. In 1894 he was seconded to Guiana and gained a great reputation among onists and inhabitants for his skill as an obstet- His main interest was, however, in tropical ne, and he performed a vast amount of patho- work in Georgetown, much of which was later ied in his book, "Tropical Medicine and ne" (1907–12). He had a large share in starting ritish Guiana Medical Annual Reports, a useful ation to which he was a frequent contributor. s the first to draw attention to the variation in ight and volume of certain organs—notably the in tropical and temperate climates, and in nd 1897 he discovered the adult worms of *demarquayi* and *ozzardi*, later finding those of *stans* also. The specimens were sent home to trick Manson, at that time medical adviser to lonial Office, who was able to add a more description of them. In 1899, at Manson's request, Daniels was appointed by the Royal Society to go to Calcutta to study the life-cycle of proteosoma in culex, and within three months he was able to confirm the work of Sir Ronald Ross in every particular. Proceeding directly from Calcutta to Nyasaland he became a member of the Royal Society's commission on blackwater fever, and together with Stephens and Christophers, was able to accomplish a fine piece of work. He himself suffered from two attacks of blackwater.

From Africa Daniels returned to London as superintendent of the School of Tropical Medicine, succeeding Dr. D. C. Rees. He was particularly successful in conducting the new enterprise, but in 1903 left England again to become first director of the Institute for Medical Research at Kuala Lumpur, in the Malay States, his place as superintendent of the London School being taken by Dr. G. C. Low. His energies in Malaya were attracted by the problem of beri-beri, but it was not many years before he was back in London at his old post. There he remained until 1910, when he took up consulting practice; by this time he had become physician to the Hospital for Tropical Diseases and lecturer on the subject at the London Hospital, at the London School of Medicine for Women, and at St. George's Hospital. In 1912, on the retirement of Sir Patrick Manson, he was appointed an adviser to the Colonial Office, and held this post until 1920, when ill-health made it necessary for him to lead a quiet life in the country. For eight years he suffered from gradual and distressing disablement, and those who knew him during the last part of his life will chiefly remember him for the uncomplaining fortitude with which it was borne.

Dr. Daniels played a very considerable part in founding the practical teaching of the London School of Tropical Medicine. He was a good teacher, possessing an especially clear and direct style, and his influence on students was profound. Sound judgment and a critical mind were reflected both in his clinical and his literary work. "He was a very straight man in every way," writes a colleague, "and never went back on his word. Though he had his likes and dislikes he never spoke unjustly of anyone, nor did he ever run people down behind their backs. He was averse to pushing himself or advertising himself in any way. If he had done so he would have occupied a higher position than perhaps he did, but to the true scientist work comes first and position only second."

Dr. Daniels married the daughter of Mr. William Slater. During his later years he lived at Ilford.

HARRY WILLIAM PIERPOINT, O.B.E., F.R.C.S. ENG., D.P.H. CAMB., LIEUT.-COL., I.M.S.

THE untimely death of Colonel Pierpoint will deeply touch the large circle of friends, Indian and European, whose affection he had gained. Born in 1879, Harry Pierpoint studied at Liverpool, and after taking his conjoint qualification in 1902 became house surgeon at the Royal Infirmary, and then in succession junior demonstrator of anatomy and demonstrator of pathology, in each case holding a fellowship of high distinction. A year after taking his F.R.C.S., in 1905, he received his first commission in the Indian Medical Service, when he was placed in medical charge of the 51st Sikhs (Frontier Force) and acted as civil surgeon to the Khyber Agency. Early in his career he became attached to the political department of the Government of India and much of his service was spent in the Native States and in Persia where before the war he travelled as a member of the International Commission which delimited the Turko-Persian frontier. He stood out as a fine linguist in a service of high linguistic attainment, and his knowledge of Persian, Afghani, and Urdu, combined with personal fearlessness, took him into regions which Europeans rarely entered. His knowledge of medicine covered a wide field, his greatest interest, as befitting a Liverpool graduate, being in orthopædics, and it fell to his lot during the war, at first in association with Colonel

H. Hallilay as commandant, later as commanding officer himself, to organise the great war hospital at Ambala, where he installed elaborate orthopædic and electrical appliances with no aid but that of native mistris from the bazar. This excellent work was rewarded with the O.B.E. in June, 1919. One who was associated with him at that time writes: "Pierpoint was constantly evolving new ideas and exploring lines of investigation suggested by them, but although a clever and virile writer his extreme modesty and hatred of publicity did not permit him to make those contributions to medical literature that his attainments warranted. He was simple and unassuming, but had the faculty of arousing deep affection in almost all who came in contact with him. If he had any enemies, it must have been because of his hatred of injustice and his fearlessness in expressing his views. Among his intimate friends he was the best of company, gay, even volatile, humorous, interesting, and full of charm."

WILLIAM JONES GREER, F.R.C.S. IREL., D.P.H.

Dr. Greer, who died at Newport, Monmouth, on August 2nd, in his fifty-seventh year, was the son of Jones Greer, of Armagh, and was educated at the Royal School there and at the Queen's Colleges of Galway and Belfast, studying medicine later at the Royal College of Surgeons in Dublin. He qualified in 1891, taking his surgical fellowship four years later, and settled in Newport, where he was at first certifying factory surgeon and later medical referee under the Workmen's Compensation Act, while he soon secured appointment on the surgical side of the Newport and Monmouthshire, Pontypool and Blaina Hospitals. From the first he took a keen interest in the diseases and accidents of the industrial community in which he had made his home, and it was fitting that he should be asked by the British Medical Association to preside over the Fractures Enquiry Committee instituted in 1912. The experience there gained may be read in an admirable article on fractures contributed to the "Index of Prognosis" in 1919, in which the economic loss from imperfect treatment is fully set out. A major in the R.A.M.C. (T.), attached to the 3rd Western General Hospital, he was occupied during the war as special surgeon in the military hospital set up at Newport. His other surgical publications include papers on gastro-jejunostomy and fibrous tumours of the mesentery.

FELIX COULSON VINRACE, M.D. R.U.I., F.R.C.S. ENG.

Mr. F. C. Vinrace, who died on July 26th at the age of 69, was the founder of St. Paul's Hospital for Skin and Genito-Urinary Diseases and for 29 years served the institution as surgeon. His father, Dr. John Vinrace, practised in Birmingham for half a century and had four sons who entered the medical profession. Felix Vinrace was educated at King Edward's Grammar School, at the University of Birmingham, and at Queen's College, Galway. He also studied medicine at University College and at the London Hospital, from which he qualified as M.R.C.S. in 1879. Two years later he graduated as M.D. and in 1886 he became F.R.C.S. The period that followed was spent in gaining a wide general experience; he held appointments as medical officer to the Hospital for Women, Soho, demonstrator of anatomy at the London Hospital, and house surgeon, house physician, and resident obstetrician at several Birmingham hospitals. In 1887 he joined the honorary staff of the Birmingham Skin and Urinary Hospital for which he worked actively for 32 years, being elected consulting surgeon in 1921. In 1898 he started St. Paul's Hospital, in Holborn, for the treatment of genito-urinary, cutaneous, and venereal diseases, and here again gave excellent service both as visiting surgeon and later as president. The success of the hospital, which was the first of its kind in this country, has largely been due to his enthusiasm and it owes much to his personal generosity. Mr. Vinrace's knowledge both of medical technique and of hos management was constantly being reinforced visits to foreign institutions, and during the 30 years he had travelled regularly on the Conti with this object. He practised as a consultant in London and Birmingham.

Mr. Vinrace was a bachelor. One of his brot is Dr. Dennis Vinrace, of London.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—names of the new members admitted to the College, a the officers of the College appointed for the ensuing at the Comitia held on July 28th, were published in LANCET last week. At this Comitia the following comm were appointed:—

Members of the Library Committee.—Dr. Frederick P. W Dr. Herbert R. Spencer, Dr. William C. Bosanquet, Dr. Hector C. Cameron.

Curators of the Museum.—Dr. John M. Bruce, C.V.O., Sir Seymour J. Sharkey, Dr. William Hunter, and Charles E. Lakin.

Finance Committee.—Dr. John Fawcett, Sir John Fr Harpin Broadbent, and Dr. James Hugh Thursfield.

Examiners.—Chemistry: Dr. Robert H. A. Plimmer Dr. William H. Hurtley. Physics: Mr. James Ha Brinkworth and Dr. Sidney Russ. Practical Pharm Dr. Nathan Mutch, Dr. William J. Adie, Dr. Gainsborough, Dr. Victor James Woolley, and Dr. Or Inchley. Physiology: Dr. Bertram J. Collingwood Dr. Swale Vincent. Pathology: Sir Frederick Andrewes and Dr. Charles Bolton. Anatomy: Grafton E. Smith. Medical Anatomy and Principle Practice of Medicine: Sir Percival Horton-Smith Ha Dr. Arthur G. Phear, Dr. Herbert S. French, Sir Jo Briscoe, Dr. John A. Nixon, Dr. Frederick S. Lang Dr. Charles E. Lakin, Dr. David Henriques de S Dr. Francis M. R. Walshe, and Dr. James A. To Midwifery and Diseases peculiar to Women: Dr. Cut H. J. Lockyer, Dr. Eardley L. Holland, Mr. Ma Donaldson, Dr. William Gilliatt, and Dr. Stanley Public Health: Part I., Mr. John H. Ryffel; Par Dr. Charles Porter. ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, AND ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The following candidates have passed the Triple Qualification examination :—

FINAL EXAMINATION.

C. S. Ramachandran, A. W. M. Battersby, S. B. Stoker, A. S. Speirs, A. G. Young, C. J. Peoples, K. C. Voon, B. F. Lewin, F. X. Oliveiro, Alice Law, H. J. Marcelin, J. D. Cooper, H. C. Duncan, D. J. Campbell, J. B. J. Cameron, J. L. Thomson, William Moodie, S. K. Rigg, H. S. Strachan, Rangachari Padmanbhachari, J. W. Galloway, H. N. Maclachlan, Theodore Lipschitz, Dorothy J. O. Mitchell, L. M. Green, C. J. P. Paglar, J. G. Buchanan, A. G. Couston, E. M. Stone, R. G. McInnes, H. A. Brentnall, G. R. Day, Edwin Amarasinghe, H. D. M. L. Murray, and V. H. Leigh-Barlow.

Medicine.—P. G. Sawmy, G. M. Johnson, T. A. W. Wilson, Eileen McCabe, G. W. Milledge, R. S. Sawani, N. C. D. Gupta, G. D. Roche, Sandaman Sivalingham, C. D. C. Golding, K. R. Trembath, Walter Campbell, A. B. Xuma, and F. A. Buttner.

Surgery.—George M. Johnson, E. P. N. Abeysundere, T. B. Dobson, S. E. W. Boland, Ram Chandra Adhikaju, K. R. Trembath, Samuel Jurawan, Suppiah Kanagalingham, J. E. Mulholland, Tan Chong Yan, and W. T. A. Pearce.

Midwifery.—Puravasthu Gopaula Sawmy, T. B. Dobson, J. S. T. Isbister, G. W. Milledge, Ram Chandra Adhikaju, Raghbir Singh Sawani, Nripas Chandra Das Gupta, James Masilamani, F. H. Emery, G. D. Roche, Sandaman Sivalingham, Maurice Klar, C. D. C. Golding, Sunderdas Tulsidas Sodah, Samuel Jurawan, Suppiah Kunagalingham, W. T. A. Pearce, Walter Campbell, I. McG. Chisholm,

J. B. Forrester, Friedrich Adalbert Buttner, J. E. Felix, and J. W. A. M. McGuinness.

Medical Jurisprudence and Public Health.—Iskander El-Aroussi. H. T. Chapman, A. H. Fraser, Chee Juay Poh, A. B. P. Amies, Adbel Kader Mohamed Attia, Okunade Ajibade, Alexander Arnott, William Wallace, Florence Letitia Macdonald Millard, F. K. Fenton, B. A. Noel de Souza, H. A. Shakerley, R. D. Buckner, Chrysostom Joseph, Raghbir Singh Sawani, Sandaman Sivalingham, and Neil Mortimer Vallely.

UNIVERSITY OF LONDON.—At a meeting of the Senate held on July 20th the title of assistant professor of anatomy at University College was conferred on Dr. Henry Albert Harris.

Grants were made out of the Thomas Smythe Hughes Medical Research Fund to Prof. Mary Lucas Keene, M.B., and Evelyn Hewer, D.Sc., for the continuation of their investigations of the human fœtus, and to Kathleen Chevassut, M.Sc., for the continuation of research on the cerebrospinal fluid.

The Council for External Students has elected Dr. Graham Little to be its chairman for 1927–28, and Sir Holburt Waring and Sir Wilmot Herringham have been elected chairmen of the Finance Committee and the Committee of Medical Members of the Senate respectively.

CRUMPSALL INFIRMARY, MANCHESTER.—A new wing has been added to Crumpsall Infirmary, one of the largest Poor-law institutions in the country, and was formally opened on August 4th by Prof. A. H. Burgess, surgeon to the Manchester Royal Infirmary, who was at one time resident medical officer at Crumpsall and was afterwards for ten years a visiting surgeon.

UNION FOR SMALLER HOSPITALS.—A united council has been formed consisting of hospital representatives with the object of raising money for the smaller hospitals by combined schemes, which will not interfere with the ordinary income of individual hospitals. It is hoped to create a foundation fund of £20,000 to inaugurate the making of the scheme, and the council is organising a united hospitals pageant and festival at Olympia next year.

EGYPTIAN MEDICAL CONGRESSES.—The Royal Egyptian Legation draws attention to the fact that no connexion exists between the Medical Congress which the Egyptian Government proposes to organise in Cairo about December of 1928 and what is called Les Journées Médicales organised for the *Revue Pratique des Maladies des Pays Chauds* by Dr. Zeitoun. Particulars of the latter conference, which will be held in December, were published in THE LANCET of April 30th (pp. 939, 952).

GUY'S HOSPITAL.—The annual report of Guy's Hospital for 1926 records with uneasiness a deficiency of £24,000 in last year's income and expenditure account. In "a year of normal income and no abnormal outgoings this is an obvious danger-signal; re-endowment must still be an aim. If another £500,000 can be added within a reasonable time to the re-endowment fund, Guy's Hospital, while still offering a field for the charitable, would be able to dispense with those urgent calls for help which by iteration detract from the force of their urgency." The opening of the artificial sunlight department has appreciably increased the out-patient attendances during the year. An average of 80 patients have attended the department daily and 23,951 treatments have been administered.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—An all-day course in medicine, surgery, and the specialties will be held at Queen Mary's Hospital, Stratford, from August 29th to Sept. 10th. All the departments of the hospital will be open continuously to those enrolling, and the course is intended for practitioners who wish to refresh their knowledge (fee £3 3*s.*) or £2 2*s.* for either week. The subjects of special courses in September will be: medicine, surgery, and the specialties, at the Westminster Hospital, all-day course (fee £3 3*s.*), diseases of children, at the Queen's Hospital, all-day (fee £3 3*s.*); ophthalmology, at the Royal Westminster Ophthalmic Hospital, afternoons only (fee £4 4*s.*); orthopædics at the Royal National Orthopædic Hospital, all-day mostly (fee £2 2*s.*); and psychological medicine at Bethlem Royal Hospital, bi-weekly lecture-demonstrations for one month (fee £1 1*s.*). Besides these special courses the Fellowship provides a general course of instruction at the associated hospitals. Further particulars of this and also copies of all syllabuses and of the *Post-Graduate Medical Journal* (annual subscription 6*s.*, post free) may be had from the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

THE late Lady Henry left by will, among bequests, £10,000 to St. Thomas's Hospital and £2 University College Hospital.

ST. THOMAS'S HOSPITAL DINNER.—The a dinner of old students of St. Thomas's Hospital w held on Friday, Oct. 28th, at St. Thomas's House, La Palace-road, at 7.30 P.M. for 8 P.M., Sir Charles A. Ba in the chair.

THE LIVERY COMPANIES AT GOLF.—A silve bowl to be known as the "Prince Arthur Cup" has presented for competition at golf between the Companies of London, to commemorate the 250th an sary of the Coachmakers' Company under their p charter, and the honour done to the Company by H Prince Arthur of Connaught joining it and becomi Assistant. It has been decided that a competition s take place at Walton Heath on Oct. 5th by bogey foursomes, each Company to send a team of six, and f particulars will be issued in due course.

All competitors must be Freemen of the City of Lo The Society of Apothecaries being one of the City I Companies, its members, provided they have taken u Freedom of the City, are eligible to take part i competition. Any who would like to do so should municate particulars of their handicap to the Clerk Society, Apothecaries Hall, Water-lane, E.C., or t Vincent Dickinson, who will be in charge of the arrange for the Society.

Notes, Comments, and Abstracts.

A HEALTH REPORT FROM NIGERIA.

IN the report for 1926, signed by Mr. K. L. Hall, acting senior assistant secretary, it is stated that during the year there has been a notable absence of epidemics of relapsing fever and cerebro-spinal fever and small-pox such as occurred during previous years; the only exceptions being Ondo Province and Keana in Benin Province, where moderate outbreaks of relapsing fever occurred during the year. Cases of yellow fever were reported from Warri, Oshogbo, and Lagos in the southern provinces. The Rockefeller Yellow Fever Commission, now instituted at Yaba, Lagos, provided Noguchi protective vaccine, and all Europeans who desired were vaccinated. A special effort has been made to organise anti-mosquito measures. In Lagos the numerous small craft plying in the harbour and creeks have been subjected to special attention, as they have been found to provide ready breeding places for stegomyia.

Throughout the year plague continued epidemic in the town of Lagos and in the province of Ijebu-Ode. In Ijebu on the mainland the chief centre for plague is the town of Ijebu-Ode, but cases have been reported from numerous other towns in the province. In Lagos the number of cases of plague showed a short rise in March, and from the beginning of July there was a gradual rise which became more pronounced during October. From the latter part of October to the end of the year there was a very decided fall in the numbers. This rise and fall was accompanied by a similar rise and fall in the percentage of rats found to be suffering from plague. The majority of the cases were of the bubonic or septicæmic type, but a few patches of primary pneumonic cases occurred. In one of these the medical department lost a European surgeon and two African nurses, all infected from the same patient.

A League of Nations Study Tour.—In May the party of medical men organised by the League of Nations to take part in a tour of the West African colonies arrived in Lagos. Belgium, France, Spain, Portugal, Guatemala, South Africa, and Britain appointed medical men to take part in it. Sir Edward Thornton, who was appointed by the South African Government to coöperate, at the request of the Nigerian Government and with the permission of the Secretary of State and the South African Government, revisited Nigeria to examine the plague situation and to report on the most effective methods of dealing with it. As a result of his report, a special plague staff has been appointed to work under the control of Dr. W. Allan, senior officer of the sanitary branch of the medical department. A special R.A.M.C. staff, consisting of two majors and two captains, has been brought out to Nigeria, and the European sanitary inspection staff has been increased by 32 R.A.M.C. non-commissioned officers and privates. These are all employed in the anti-plague measures now being carried out in Lagos and Ijebu Province.

Vaccination continues to be actively pushed as a preventive against small-pox. The percentage of successful vaccinations is about 64. Quinine as a prophylactic against malaria has been distributed, particularly in the central province. The work on the investigation of the tsetse-fly and trypanosomiasis has continued throughout the year in the northern provinces. The centre of operations is at Sherifuri, in Kano Province. In addition to clearing of bush and thickets near pools and along the banks of rivers, experiments in late burning of the bush were carried out. As the effect of the first experiment in late bush burning on the prevalence of the fly was inconclusive, further experiments will be carried out next dry season.

The population of Nigeria (including the mandated area of the Cameroons), according to the latest returns, is 18,502,322 larger than that of any British dependency except India. There are about 4000 Europeans temporarily resident in Nigeria, chiefly in the employ of the Government and of mercantile and mining companies. The country is not suited for European settlement. Of the native inhabitants the greater number are of pure negro race, but in the north there are Berber and negroid tribes. The area of Nigeria is approximately 367,837 square miles. This includes the mandated portion of the Cameroons (31,150 square miles).

BITE OF A MADD DOG.

AN ancient recipe against rabies, dating probably from the beginning of the eighteenth century, is that of a certain Mr. John Barnardiston. It has been preserved among some 70 old manuscripts in the library of the Royal College of Surgeons of England, of which many were sent at different times to the College authorities by lay wellwishers anxious to impart to the professional mind useful information that might have escaped its notice. "You are to take six ounces

of rew," says Mr. Barnardiston, "four of garlic, four of mithrydate or treacle, four of scraped pewter or block tin; you are to boil these for the space of an hour in a closed pot, and give luke warm eight or nine spoonfuls to a man or woeman, in the morning fasting, 15 to a horse or cow, three to a sheep, and foure to a dogg. If any wound lay some of the dreggs to it, and 'twill heale it. Give it thre mornings following and then intermit thre, and so from thre to thre, till you have given it nine times."

The number nine strikes the note of magic, and this is emphasised in the next sentence: "If you have any faith in Charms the following words wrott on a peece of Cheese, and given the Dogg that's bitten I am told, has done wonderful cures.

Alnis, Alnis, Apelbusque
Arribas, Arribas, Apelbeseque
or
Carnis Darnis Farnis
Farnis Darnis Carnis.

"I depend upon none of these fooleries," adds the writer, doubtless in deference to the rationalism of his times, "but the first if timely given to my own knowledge is a certain cure." Mr. Barnardiston may be imagined as a kind of Will Wimble, writing to a patron, a second Sir Roger de Coverley, to whom he is perhaps related. "Pray, Sr, remember poore Pompey be sent to your cosen . . . who promised me he'd take care the Fellow I spake to should make him." The last phrase suggests, however, that Pompey is not a dog, but an inanimate object. "My service attends all the good Family," ends the writer.

The mystery of hydrophobia continued to puzzle the eighteenth century to the last. Charms were perhaps abandoned towards its close, but magic was still resorted to in domestic pharmacology. In the chapbook "A Thousand Notable Things, disclosed from the Secrets of Nature and Art, practicable, profitable, and of great advantage," which was published as late as 1791, we are gravely informed that "Hens Dung mixed with Meat that is given to be eaten of Mad Dogs, will take away their Madness from them (as it is thought)."

INFAMOUS CONDUCT.[1]

THE hope of the author is that the publication of an array of startling facts may bring about a reformation of the terms of censure passed by the General Medical Council upon transgressors, and the title which he has chosen puts him in a favourable position as a critic, for nobody defends that particular phrase in the Medical Acts, while very few persons have taken the trouble to find out how it got there. The story consists of a long series of episodes, any one of which may have occurred in the conduct of one medical practice, but few of which are likely to occur with any frequency in the practice of one man—the lamentable consequences which, following an unbroken sequence of disasters, form a category accordingly which is highly improbable. To use the events of such a peculiar medical career as an argument for "the reform of arbitrary rules and regulations relating to medical practice" is not logical; further, to make the argument for reform forcible the reiteration of misunderstanding and tragedy has turned what with due sense of proportion would have been a pathetic story into a wearisome one. The arrangement of the catastrophes in order to accentuate the drawn-out tragedy is so monotonous as to prevent all illusion that we are being presented with a picture of life, even though we may be familiar with the fact that any of the events might happen. The book is sad, earnest, and well-written, but not likely to stir unconvinced readers to agitate for reforms.

WELFARE OF MINERS.

IN the Northumbrian coalfield the Ashington Coal Company holds a premier place both by its size and by its reputation for efficiency combined with genuine care for the well-being of its 10,000 employees. The plant is up to date; underground roads are well kept and well supported, electrical coal-cutting is extensively practised, the screening apparatus is of the best, and the coal is sent in 20-ton wagons to the neighbouring port of Blyth. Ashington itself, a town of some 30,000 inhabitants, does not differ notably from any other mining town in the north of England, but three miles away, at Lynemouth, the company has built a model village, laid out by the seaside and comparing well with anything built in the newer coalfields. Many of the houses are being purchased by the tenants under a 15-year rent-purchase scheme. By arrangement with the Miners' Welfare Fund, pithead baths have been installed at two of the collieries of the group, the money required being advanced in the first place by the company. The baths are fairly well used, though there is some conservatism to contend with. The same conservatism has shown itself in connexion with the housing scheme at Lynemouth, where it was necessary to instal the old-fashioned wasteful open r instead of modern stoves. The Ashington Coal Co has, of course, been involved with all the other c companies in the labour disputes of recent years. is a fair surmise that if all collieries had been as compe and as humanely managed the position of the coal ind to-day would be very different.

GOITRE AMONG MANCHESTER CHILDREN

FURTHER investigation into the incidence of goitre a elementary school-children is recorded by Dr. O Taylor in the latest annual report of the school m officer for Manchester. The number of children exa was 13,578 (6396 males and 7182 females), and all en ments of the thyroid were included, whether slight apparent on inspection) or considerable. No line drawn between pathological and physiological enlarge The distribution of goitre was found to vary wit nature of the superficial deposit over the triassic marl sandstone on which Manchester lies. The endemicit found highest where the surface deposit is largely clay (pe age incidence 8·8 in boys and 11·3 in girls), and lowest the surface is glacial sand (3·7 in boys and 5·5 in It was noticed that whilst many Jewish children att the school clinics for various ailments, none attend account of goitre. Among the Jews 1675 boys and 180 were examined. Enlargement of the thyroid glan found in 0·4 per cent. of the boys and 1·2 per cent. girls. None of these 3483 children were more than sl affected. In one school, where 95 per cent. of the and 80 per cent. of the girls were Jewish, two boy nine girls of Gentile stock were found to show enlarg of the thyroid and only one Jewess exhibited any si goitre. In another school largely attended by J children ten cases of thyroid hypertrophy were found a the Gentiles but none among the Jews. "It seems c says Dr. Taylor, "that the endemicity among the J children is low when compared with the prevalence a Gentiles living in the same neighbourhood attendin same schools and drinking the same water. Many Jewish children in Manchester are of Russian origin, an eat rye bread of a dark coarse texture. It appears, mor that they eat more fish and poultry but less beef than Gentile neighbours. The more indigestible pork eschew on religious grounds. The pregnant Jewess i cared for. Alcohol is not allowed, nor is she suppos engage in outdoor employment from the beginni pregnancy till the completion of lactation. As a ru Jewish child is breast fed."

ESPERANTO AND MEDICINE.

AT the official Esperanto Congress which has just its session in Danzig, reference was made to medical this language. There are some 700 medical men distr through 26 countries who use the language and who su a well-printed Esperanto medical magazine, the *Int Medicina Revuo*. During the proceedings of the Co it was stated that the Medical Academy of Toky unanimously adopted Esperanto as the official langu which a number of monographs by professors Pathological Institute of the Imperial University of have already been printed. Some of these works, as reprints from the *Japanese Journal of Dermatolo Urology*, can be seen at the offices of the British Esp Association, 142, High Holborn, London, W.C. 1. terms are already to be found in the larger Esp dictionaries, but for the use of doctors an official medical words is being compiled and published *Internacia Medicina Revuo*, while a list of drugs, co from 16 different pharmacopœias, with a common Esp translation, has been published in a report of a comm on pharmacological nomenclature. In a note in *Intern Language* on the use of the microphone to facilita translation of speeches at international congresses, a co language such as Esperanto is advocated, and in th nexion it is interesting to see that in Europe, Asia, Au and America there are 30 or more radio stations re broadcasting Esperanto lessons or talks.

HOSPITAL COÖRDINATION AT SHEFFIELD.—A advisory committee has met to report on hospital co tion between Sheffield, Bakewell, Barnsley, Don Denaby, Mexborough, and Worksop.

MANCHESTER BABIES HOSPITAL.—The incre the number of beds has, says the annual report, neces a corresponding increase in the work of the doctors a staff, and to meet this new appointments have been A junior resident medical officer, a second masseus a biochemist have been appointed.

An Address

ON THE TREATMENT OF GENITAL TUBERCULOSIS IN THE MALE.

Read in Substance at the Third Congress of the International Society of Urology Meeting in Brussels, August, 1927,

BY KENNETH M. WALKER, F.R.C.S. ENG.,

SURGEON IN CHARGE OF THE GENITO-URINARY DEPT., ROYAL SOUTHERN HOSPITAL, LONDON; SURGEON TO ST. PAUL'S HOSPITAL.

THE surgical treatment of tuberculosis, if it is to be logical, must be based on a knowledge of the pathology of the disease and of the manner in which various organs are infected. Unfortunately, in the case of tuberculosis of the genital tract this knowledge is lacking. Doubt still exists as to whether the epididymis or the seminal vesicle is the first to be infected, and as to whether the spread is an ascending one from epididymis to prostate or a descending one from prostate to epididymis. Both schools of thought have their adherents, and, in spite of all the investigations carried out to settle the question, no final decision has been reached. This absence of exact pathological knowledge of the disease is reflected in the confusion that exists in our surgical treatment. Whilst some authorities confine surgical intervention to such minor proceedings as the opening of abscesses or the carrying out of an epididymectomy, others believe that as the primary lesion is in the prostate or vesicles and not in the testicle the logical line of treatment lies in removal of the vesicle in addition to the epididymis. It is impossible, therefore, to discuss the surgery of genital tuberculosis without first referring to its pathology.

ASCENDING AND DESCENDING THEORIES.

The view that genital tuberculosis is an infection which appears first in the epididymis and thence extends to the prostate and vesicles is based mainly on three sets of observations—namely, the frequency with which tuberculous epididymitis is found without there being any clinical signs of a prostatic or vesicular lesion, the rarity of primary prostatitis or vesiculitis, and the failure on the part of such experimenters as Baumgarten and George Walker to produce in animals a descending infection. If we examine these foundations of belief we shall find that they are perhaps not so secure as they might at first sight appear. Personally, I feel that the failure on the part of clinicians to discover lesions of the prostate or vesicles in cases of tuberculous epididymitis is due to the fact that tuberculosis, when it affects these structures, gives very little evidence of its existence. At the most the patient complains of a mild frequency or irritation in micturition, and when examined per rectum nothing may be found in the early stages beyond a slight induration of the vesicles. For the same reason cases of tuberculous epididymitis or vesiculitis rarely consult a doctor until the appearance of a swelling of the testicle calls their attention to the fact that something is wrong. If, however, a very careful rectal examination be made in all cases of tuberculous epididymitis, and the smallest departure from the normal noted, whether it be in the shape of induration, tenderness, or pus in the expressed secretions, it will be found that very few cases can the prostate or vesicles be said to be normal. In a series of 30 cases so examined by me I found only three in which the prostate and the vesicles gave no evidence of the disease, although it must be confessed that frequently there existed no proof in the remaining cases that the prostate or vesicles were necessarily tuberculous, all that could be affirmed being that they were the seat of some inflammatory process. Mr. H. H. Young, in a larger series of 222 cases of genital tuberculosis, found only 37 in which no lesions of the prostate or vesicles could be detected, but in 47 cases he found that these structures were implicated alone. Keyes goes so far as to state that in every case of tuberculous epididymitis examined by him during the last ten years he has been able to find some indications of a pathological condition of the prostate.

Post-mortem observations are unfortunately of little assistance in helping us to a decision as to the spread of genital tuberculosis, first on account of the fact that in the post-mortem room only advanced stages of the disease are seen; and second, because in the opinion of most pathologists it is impossible to deduce the direction of spread by noting the apparent age of different foci. All that the post-mortem room can teach us with any degree of certainty is that in the vast majority of cases of genital tuberculosis the whole of the genital tract is invaded.

ANIMAL EXPERIMENTS.

The third foundation of the belief that genital tuberculosis is an ascending infection is the experimental work done by Baumgarten and, later, by George Walker. These investigators found that although it was easy to obtain secondary infection of the prostate and vesicles after inoculation of the epididymis of a rabbit with an emulsion of tubercle bacilli, it was difficult or impossible to bring about a spread in the opposite direction by inoculation of the posterior urethra or walls of the bladder. In a series of 20 rabbits whose bladders were inoculated with tubercle bacilli by Walker there were only two cases in which the epididymis subsequently became tuberculous, and he puts forward the view that in these two animals the infection probably took place through the blood stream rather than along the vas.

In 1912 I repeated Baumgarten's experiment, but, before placing tubercle bacilli in the urethra, took the precaution of subjecting the right testicle to a certain amount of trauma by exposing it and squeezing it. The history of the rabbit was as follows: two days after inoculation of the urethra with tubercle bacilli a hydrocele appeared on the damaged side, the scrotum became red and œdematous, and the whole testicle felt large and tender. The maximum size was attained at the end of four days. After this there was a gradual diminution in the size of the testicle, and the hydrocele subsided. At the end of a fortnight the rabbit was seen to be suffering from an undeniable tuberculous urethritis. Small white tubercles appeared on the glans penis in the region of the meatus, and about the same time the epididymis on the side which had been damaged again became enlarged, hard, and nodular to the touch. At the end of six weeks the epididymis felt still more nodular and had increased in size. As the animal was beginning to lose flesh it was decided to kill it in order that the condition might not be complicated by the addition of generalised tubercle. At the post-mortem it was found that this undesirable complication had not been entirely averted, for five or six small tubercles were seen on the peritoneum. However, in the region of the damaged testicle massive lesions were present, and there was a marked thickening of the vas on this side. The distribution of the lesions in the vas was the same as that which is usually found in the human subjects—namely, marked thickening of the testicular and prostatic extremities with very little thickening of the intervening portion. There was also obvious disease of the vesicle on the same side, and ulceration of the urethra and neck of the bladder. I am aware that the weak point of this experiment is that there is no proof that the infection of the testicle occurred via the cord and not via the blood stream, but the massive infiltration of the epididymis commencing a few days after inoculation, and long before the rabbit had begun to lose weight, was certainly suggestive of a direct extension rather than of a late blood infection.

Baumgarten put forward the view that the reason why descending tuberculosis did not occur was that

the tubercle bacillus was a non-motile organism and consequently had no power of travelling down the cord against the current of testicular lymphatic secretions. But such an objection would apply equally to the gonococcus and to other organisms that are known to take such a path. Indeed, it is difficult to understand, in view of the close resemblance between chronic gonococcal epididymitis and tuberculosis, why a different pathology has been accorded to the two infections. Why is it that in one case the organism is supposed to reach the epididymis through the cord and in the other through the blood stream? Is it not a well-known fact that blood infections of the testicle—e.g., in syphilis, mumps, and typhoid—almost invariably affect the body of the testis rather than the epididymis? All observers now agree that it is in the lower pole of the epididymis that tuberculous deposits first appear, and this is the portion of the epididymis that would first be reached by any organisms descending the cord.

SURGICAL TREATMENT OF GENITAL TUBERCULOSIS.

The operative treatment of genital tuberculosis ranges from purely palliative measures, such as the opening of abscesses and the scraping of sinuses, to such radical procedures as complete removal of the seminal tract. Of some of the operations that have been practised in the past, such as bilateral castration, it should be unnecessary to speak, since they have been abandoned by all reputable surgeons. Nevertheless I have seen patients during the last ten years who have been treated by bilateral orchidectomy with the result that to their physical disabilities has been added a serious neurosis directly resulting from the loss of both testicles. Total removal of the testicle, even on one side, should never be carried out unless the body of the testis has been invaded to such an extent that any attempt to save it is out of the question. Fortunately, the testis shows considerable resistance to tuberculous invasion so that it is generally only in advanced cases that it becomes affected. Young states that the testis was only involved in 8·3 per cent. of his cases, although it must be admitted that Barney gives a considerably higher figure. Unnecessary sacrifice of a testis not only deprives the patient of the benefit of its internal secretion, but inflicts on him a severe psychological shock. The removal of an infected epididymis, on the other hand, is accompanied by very little psychological shock since the patient feels that the testicle is still present and can face with equanimity the subsequent discovery of disease on the opposite side should this occur. This spread of tuberculosis to the opposite epididymis is, of course, a feature of the disease, and is in my opinion a strong argument in favour of the primary focus being situated in the centrally placed structures, the prostate, or vesicles. I can find no evidence in my own statistics, or in those of others, that orchidectomy offers any greater protection to the opposite testicle than does epididymectomy, and for this reason I prefer the latter operation in all cases except where the testis itself is extensively involved.

A second point on which many surgeons differ is as to the amount of vas that should be removed with the diseased epididymis. Whereas some content themselves with removal of the vas as far as the external ring, others advise opening the inguinal canal and removing as much of the vas as can be reached by this fresh exposure. If the vas is felt to be thickened, it is, of course, a wise proceeding to remove it with the epididymis, but in the majority of cases it will be found that this thickening only extends along a few inches of its length. As a result of examining a great number of cases, both in the operating theatre and the post-mortem room, I have found that the portion of vas which is most rarely affected is its middle third. Indeed the distribution of tuberculous infiltration along the vas is a matter of considerable interest not only to the surgeon but also to the pathologist. If one dissects out the genital system of a patient who has died of tuberculosis, and examines it microscopically by means of a series of transverse sections taken through various portions of the vas, one finds the following: Sections from the prostatic extremity show that the vas itself is comparatively healthy, but that it is surrounded by a thick shell of tuberculous tissue, due to infiltration of the lymphatics. As the testis is approached the lymphatic infiltration gradually ceases. A section from the distal end of the vas, near its termination in the epididymis, shows a converse condition. Here the disease has affected the mucosa of the vas, whereas the surrounding lymphatics give little or no evidence of any lesion. This distribution suggests that the disease is disseminated from the prostate by the lymphatics, and that having encountered in the epididymis a suitable soil in which to flourish, it produces a returning wave of infection in the vas, through the agency of the secretions. It is interesting to note that the microscopic examination of the genital tuberculosis experimentally produced in the rabbit by urethral inoculation and described above showed an exactly similar distribution, the prostatic extremity of the vas and the seminal vesicle on the diseased side being enclosed in a dense shell of tuberculous infiltration, whilst the inner coat of the vas appeared healthy. Apart, therefore, from other considerations, the distribution of the tuberculous tissues suggests the existence in these cases of two opposing waves of infection, a centrifugal and primary one, travelling from the prostate along the lymphatics, and a centripetal and secondary one, in the lumen of the vas, due to the flow of infected secretions from the diseased epididymis. (See figure.) The practical lesson to be learnt from these observations is that it is seldom necessary to attempt the removal of a great length of vas when performing epididymectomy.

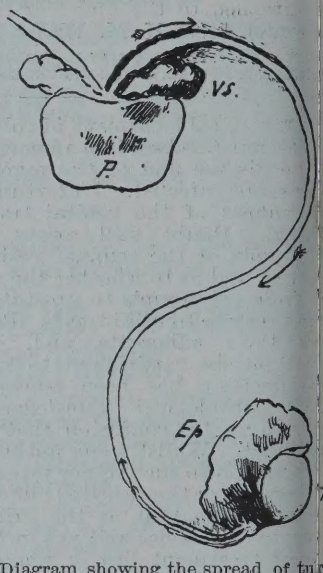

Diagram showing the spread of tuberculous infection from a deposit in the prostate. The position of the tuberculous infiltration is shown by the dark shading. At its proximal end the outer coats of the vas are mainly affected, and at its distal extremity the inner coat.

The arrows show the suggested waves of infection, a primary one from the prostate to the epididymis along the sheath of the vas, and a returning wave through the passage of infective material from the epididymis along the lumen of the vas.

Total Removal of the Seminal Tract.

It is obvious that to those surgeons who believe that the primary lesion of genital tuberculosis is centrally in the prostate and vesicles, no operative measure can be considered truly radical unless it includes within its scope the removal of the centrally placed structures. Acting on these principles Mr. H. H. Young, of Baltimore, has substituted for epididymectomy the operation of epididymo-vesiculectomy, or total excision of the tuberculous seminal tract. This operation, whatever its disadvantages is in my opinion based on a true conception of the pathology of the disease. If it is necessary to attempt to remove by the knife all infected tissues then Mr. Young's formidable operation should be done. His procedure is as follows. The prostate and vesicles are first exposed through the ordinary inverted "V" shaped perineal incision, used for perineal prostatectomy. The first steps of the operation

reed the same as for a perineal prostatectomy, but the later stages a fuller exposure of the seminal icles and the ampullæ of the vasa is required. These uctures are then freed from the base of the bladder dissection from above downwards until their ction with the upper portion of the prostate is ched. If the prostate is obviously affected it is removed by enucleation from within its capsules, the fascia, ampulla, seminal vesicles, and lateral es of the prostate taken away in one piece. The und is then partially closed, long clamps being attached to the upper divided ends of the vasa erentia for traction later. The patient is then ced on his back with legs separated and lidymectomy is carried out, the vasa deferentia g exposed up to the external ring. Then with an stant pulling on the clamp holding the divided tral end of the vasa, and the operator alternating h traction of the distal end, the intermediate portion the vas is freed from its adhesions and finally lsed. By this means a complete and radical noval of the entire seminal tract is effected with the eption of a few mm. of the terminal portion of the ulatory ducts. Mr. Young furnishes statistics of cases treated by his radical operation with only operative death, in spite of the fact that many of patients were in an advanced state of the disease some in addition handicapped by associated ons elsewhere in the body. He urges that the ration should be undertaken in all cases in which re is reason to believe that the vesicles or the state are involved in the tuberculous process, and siders that the only hope of radical cure and of pletely arresting the disease lies in this direction.

The operation of total excision of the seminal tract undoubtedly one of great severity. Not only does mean a difficult dissection of the perineum and the noval of vesicles that are generally closely adherent the bladder and peritoneum, but it entails a valescence that may by no means be without dent. In two out of the three cases in which I e performed Young's operation secondary morrhage has occurred from vessels lying high in the wound, and in one case the passage of us through the perineal wound suggested that in e of every effort to avoid injury to the rectum some ior damage had been inflicted. In this country ineal prostatectomy is rarely performed and for s reason, if excision of the vesicle and affected tion of the prostate is necessary in the treatment of ital tuberculosis, most operators will prefer the uinal approach. In this operation, after completing epididymectomy, the vas is exposed by an ique incision above Poupart's ligament, resembling t required for subperitoneal exposure of the ter. By stripping the peritoneum inwards and secting down to the pelvis, not only can the whole the vas be exposed, but also the vesicle, and the per half of the prostate. It is also possible to remove opposite vesicle through this incision and thereby inish the risk of extension of the disease to the aining epididymis. However, although to some rators this method of exposure seems preferable, re is the undoubted disadvantage that drainage ar less satisfactory than with the perineal route.

CONSIDERATION OF SURGICAL TREATMENT.

Having indicated the possible lines of surgical ervention it will be as well to consider their place the treatment of genital tuberculosis. Does the ration of epididymo-vesiculectomy offer good spects of eradicating the disease, and are its results ter than those obtained from less radical forms treatment?

Before attempting to answer these questions it is portant to remind ourselves that in the vast jority of cases genital tuberculosis is associated h active lesions elsewhere in the body, and ticularly in the urinary tract, and for this reason s impossible to deal with it as though it existed as an ated entity. Genital tuberculosis must be regarded a local manifestation of a general body condition, and this fact must never be lost sight of in any consideration of its pathology or its treatment. Cases of genito-urinary tuberculosis are now handed over to the surgeon, and it is right that this should be so, for surgery, by removing badly infected tissues, can do much to assist the body in its fight against the tuberculous invasion. But the successes of surgical intervention must not blind our eyes to the fundamental fact that the treatment of genital tuberculosis is a problem in immunity, and that rarely, if ever, can the knife completely extirpate the disease. However radical our operation, some focus must remain behind, either inside or outside the genito-urinary tract, from which new invasions may take place and fresh organs become infected. But fortunately for us, the mechanism of immunity in a patient suffering from genito-urinary tuberculosis, although impaired, is not disorganised, and the removal of the more grossly infected tissues is often sufficient to allow of its overcoming that which remains, so that the fact that it is impossible to remove all infected tissues does not mean that our operation because incomplete is useless. Every surgeon must have noted the improvement in the condition of the tuberculous prostate and vesicle that generally follows removal of the focus in the epididymis. Subsequent to epididymectomy the tuberculous deposits in the central structures become reduced in size and encapsulated with fibrous tissue. This is due both to a reduction in the amount of infection with which the body resistance is called upon to deal and also possibly to the cutting off of the flow of infecting material passing along the vas from the diseased epididymis. Even when the mode of life and environment of the patient are by no means ideal this regression of the lesions of the prostate and vesicles is generally noted, but it is, of course, much more marked if to the surgical intervention can be added general measures calculated to raise the body resistance. On *a-priori* grounds, therefore, such a serious operation as that of total excision of the seminal tract is not necessarily justified. Justification must come from the results rather than from any argument based on pathology. Does the radical operation offer the patient a better chance of cure and does it reduce the danger of extension of the disease to other portions of the genito-urinary tract? Although we find on following out the subsequent history of cases of genital tuberculosis that many of them eventually die of phthisis or of general miliary tuberculosis, death in a certain number of cases is the direct result of extension of the disease to the urinary tract. Indeed it may be said that apart from generalised tuberculosis the most distressing complication that is likely to arise in the course of genital tuberculosis is involvement of the bladder and kidneys. Does total excision of the seminal tract offer a patient better protection from such a complication than does epididymectomy, supplemented by general therapeutic measures? Unfortunately, it is difficult to obtain any figures that can assist us in coming to a decision on this point. Direct extension from the prostate and vesicles to the bladder may undoubtedly occur. It is also possible that in some cases infection may spread through the lymphatic network from these structures directly to the ureter and from there up to the kidneys. But although statistics can be found showing the percentage of cases of genital tuberculosis that subsequently give evidence of urinary lesions, it is impossible to exclude from these figures cases in which the renal focus has actually existed prior to the outbreak of the genital one. It is now recognised that a tuberculous focus in a kidney may for a long time remain latent, its presence only being made manifest when it has ulcerated through into a calyx and discharged tubercle bacilli and pus cells into the urine. That the renal focus has antedated rather than post-dated the genital tuberculosis would certainly appear to have been the case in many of the so-called examples of secondary extension to the urinary tract that have been brought to my notice. This difficulty of eliminating cases of latent

renal tuberculosis introduces so large an error into the interpretation of statistics that they become of very little value as a criterion of the comparative merits of total excision of the seminal tract, and of epididymectomy, in protecting the individual from the dangers of extension of the disease to the urinary tract However, it is only fair to add that a comparison of the figures furnished by H. H. Young, with those supplied by exponents of epididymectomy would appear to indicate that the radical operation diminishes, although it does not entirely eliminate, the risk of subsequent involvement of the urinary tract.

SUMMARY.

In the foregoing paper I have laid emphasis on the fact that although the treatment of genital tuberculosis now lies in the hands of the surgeon, the disease is not an isolated unit that can be dealt with entirely by operation, but that it must be regarded as a local manifestation of a general condition requiring the adoption of all these general and local measures that we know to be of value in raising the resistance of the patient against the tuberculous invasion. In discussing the operative treatment of genital tuberculosis I am of opinion that epididymectomy is the operation which is most generally useful. Vesiculectomy, although it is based on a correct understanding of the pathology of the disease, is, I believe, rarely necessary, since removal of the lesions in the testicles is usually followed by marked regression of those in the prostate and vesicles. This regression is materially assisted if to epididymectomy are added other methods of treatment—climatic, dietetic, and the use of heliotherapy, X rays, and tuberculin. If an improvement in the central lesions does not occur, then vesiculectomy and removal of grossly infected tissue in the prostate should be carried out as a secondary measure. In advanced cases of tuberculous vesiculitis and prostatitis, and where fistulous tracts exist, the radical operation should be performed as a primary measure. Possibly it may also be carried out in a few cases of less advanced disease where the mode of life and environment of the patient is so unfavourable that from the outset he is severely handicapped in the fight against the tuberculous invasion.

STREPTOCOCCAL PITYRIASIS.[1]

BY H. HAXTHAUSEN, M.D.,
FIRST ASSISTANT IN THE SKIN DEPARTMENT, STATE HOSPITAL, COPENHAGEN.

THERE is hardly any field in dermatology so ill-defined and so variously interpreted as the eruptions which we group together under the term *Pityriasis simplex*, or as, following Unna, this clinical picture is generally called, eczema seborrhœicum.

Now it is not my intention on this occasion to involve myself in the many different aspects of this complicated problem, but I hope with the present exposition to make a modest contribution towards its elucidation. My investigations add nothing new to our knowledge of genuine eczema seborrhœicum itself; they merely set out to prove that certain desquamating rashes, which have hitherto been classed as eczema seborrhœicum, should be excluded from this category and grouped together as a special and independent clinical entity.

The form of disease whose distinctive character I am concerned with I have called *Pityriasis streptogenes*, because the formation of scales is its most striking sign, and in view of the fact that streptococci are probably the cause of the disease. Earlier authors have already attempted to distinguish some of the cases comprised by this clinical expression from seborrhœal eczema. Thus in his well-known work, "Les Maladies Desquamatives," Sabouraud discusses certain desquamating eruptions which appear principally on t face in children and which often occur epidemical They frequently develop after impetigo, for wh reason Sabouraud regards them as a mild form of t disease. In England Adamson separated th desquamating affections occurring in the train impetigo under the heading "chronic impetigo," a they are mentioned in Sequeira's "Skin Disease and a few other places. Most authors, however, p this clinical picture in a higher category with seb rhœal eczema.

The clinical and bacteriological investigations wh I am about to relate prove, in the first place, t justification for this exclusion from seborrhœal eczer which Sabouraud, Adamson, and a few others ha attempted; but they also show that the disease is more comprehensive and far more general than o would think from the earlier observations.

METHOD OF CULTIVATING STREPTOCOCCI FROM THE SKIN.

The basis on which I propose to establish pityria streptogenes as an independent disease of the sk is a special method of cultivating streptococci from t skin. The method has previously been published, that I shall content myself with stating its princip

The method depends upon the observation that t well-known dye, crystal violet, prevents the growth the staphylococcus in such weak concentrations as not affect that of the streptococcus. It is theref possible, by adding a suitable quantity of crys violet to the various nutritive media, to get a p culture of streptococcus when this organism is mix with staphylococcus in the original material. As well known, it is impossible to demonstrate t presence of streptococci by spreading material fr the skin on the ordinary solid media, because a numb of staphylococci are always found there, wh luxuriant colonies entirely submerge the streptoco with the ordinary technique. For detecting th bacteria in the skin Sabouraud's well-known method cultivation in Pasteur pipettes has therefore hithe been employed, by which they can be obtained pure culture as facultative anaerobes from the draw out end of the pipette, while the staphylococci o grow in the upper layer of the broth.

Sabouraud's method has proved to be extrem sensitive when it is merely a question of the *demonst tion* of the presence of streptococci; but it has important defect in that it tells us nothing about t amount of streptococci in the material examined. a matter of fact, a single streptococcus, perhaps pres by chance, will give the same result with this cult method as when a number of them are present. harmony with this Frédéric and Flehme have obtain a positive result from normal skin in about 15 per ce of all cases examined, and from diseased skin a s greater number of times, so that the pipette meth has a very restricted application where it is a quest of demonstrating the significance of streptococci the cause of a skin disease.

The new method, however, with the addition crystal violet has an advantage, in that it permits cultivation on *solid media*, whereby one can form good idea from the quantity of colonies of the numb of streptococci in the original material. The mediu I have used is 10 per cent. blood-agar, to which crys violet in a concentration of 1 : 100,000 was add In nine out of ten cases any streptococci pres will grow on this medium, while staphylococci entirely or almost entirely inhibited, both when t culture is made from fluid material and from sca which are sprinkled over the surface of the agar. T addition of blood favours the growth of the streptoco and also ensures that the small, rather inconspicuo colonies are easily recognised, for a distinct hæmoly zone nearly always appears around them.

ÆTIOLOGICAL SIGNIFICANCE OF STREPTOCOCCI IN SKIN DISEASE.

I shall not on this occasion enter further into t interesting results which this method has yielded h

[1] The Annual Oration delivered before St. John's Hospital Dermatological Society on June 22nd.

petigo and various other skin diseases. These sults, which I have previously reported, have com-tely confirmed the now generally accepted view at streptococci are the cause of impetigo vulgaris. ltures on crystal violet agar in these cases almost stantly show myriads of streptococci both from ent and from old eruptions. On the other hand, accord with the general view, it has turned out that petigo contagiosa neonatorum is unlikely to be due streptococci; for although they are very often sent when cultivations are made in a pipette—ich has given rise to some doubt about the ætiology growth on crystal violet agar shows that only a few ganisms are present in these cases, presenting a ture quite different in appearance from that of petigo vulgaris. A similar result was obtained with so-called impetigo bullosa in adults, where lassohn's and Lewandowsky's assumption that phylococcus is the cause has been fully confirmed. e streptococci which can so frequently be detected the pipette method in normal skin and in definitely n-streptococcic skin diseases are also found to be sent in small numbers on cultivation on crystal let agar, for they only produce a few colonies.

The impression of numbers given by this method is appears to have a certain value when it is a estion of deciding the ætiological significance of ptococci in any skin disease, because, as stated, saprophytic streptococci are usually present in ling numbers, while the pathogenic ones produce abundant crop of colonies. It is in the light of se facts that the results I am going to communicate uld be interpreted.

A Typical Case.

Before relating the cultural experiments I should e to give a short clinical description of the disease ich I have defined by the term pityriasis strepto-ges, and as the basis of this I will begin by citing typical, uncomplicated case. It was a boy of 12 years, whose face numerous isolated desquamating spots present. They are of widely different sizes, from nute dots to the size of a coin, and the shape is gular. The elements are pink in colour, hardly ltrated at all, and they are only just raised above level of the surrounding skin. The desquamation very characteristic, the scales occurring as small aked lamellæ, giving the surface the appearance of oughed field in miniature. The characters just ntioned, with which all will be familiar from daily ctice, will alone be sufficient to distinguish the ease from true seborrhœal eczema, with which it is ften confused. But there are other symptoms which entuate the difference. Thus it is a rarity to see extensive scale formation in the scalp in these ients, while seborrhœal eczema nearly always inates and is most widely distributed in this ation. (Fig 1.)

Cultivation Experiments.

In many cases with a typical appearance such as I ve described I have made cultivations on the stal violet agar referred to, simply by scraping the face with a sterile sharp spoon and sprinkling the les on a Petri plate. It was found that this lesion ctically always harbours streptococci, and in the jority of cases in great abundance. Thus a colony requently seen to spring from almost every tiny le scattered about the plate. In cultivations on inary blood-agar from these eruptions one hardly r sees the streptococci, because their growth is pletely submerged by the staphylococcus colonies ing forth from each small scale. Only by the lition of crystal violet can the true bacteriological ure of the disease be recognised.

The cultural result described is wholly different n what is obtained in cultures from psoriasis, gworm, pityriasis rosea, and similar diseases, which rphologically have some likeness to pityriasis ptogenes. One now and then, of course, does find ptococci in these lesions, but there are never more n a few isolated colonies, just like what is obtained from the normal skin. In the drier forms of true seborrhœal eczema, also, only occasional colonies are obtained, but in the weeping forms streptococci may be present in larger numbers. In the latter instance it is undoubtedly a question of a secondary infection —of the production of impetigo so frequently seen in this disease.

The cultivation experiments therefore are greatly in favour of streptococci being the cause of the form of pityriasis described above. But from these results alone I would not venture to propose the name pityriasis

FIG. 1.

Typical case of streptococcal pityriasis with lesion starting at angle of mouth.

streptogenes for this lesion if the clinical facts did not point so definitely in the same direction. As I have already stated, Sabouraud, Adamson, and others have observed that these cases can develop from impetigo, which suggests a close ætiological relationship with this disease. One often sees, moreover, that the superficial scaly spots become the seat of impetigo, either throughout their extent or at isolated points.

Clinical Characteristics.

A point observed in many of these cases, and one which supports the view that streptococci are the cause, is their tendency to start at the angles of the mouth or the nostrils. Experience shows that these regions are haunts of streptococci, for they constitute a kind of advance station for them on their way to the skin. I will now show you one of these typical affections starting from the angle of the mouth. This clinical picture will, of course, be quite familiar to you all in your daily practice.

As I have said, the typical forms of the disease occur on the face, especially in children. But since the discovery of a method for diagnosing this complaint bacteriologically with a fair degree of certainty —namely, the cultural method described—it has been found that it also occurs in other localities in the form of a less typical eruption, and much more commonly than was previously believed. The cultural demonstration of streptococci has in a way opened our eyes to the true nature of a number of hitherto obscure desquamating eruptions, because pityriasis strepto-

genes has been borne in mind in considering these affections, and it has often been possible to detect one or more characteristics of its clinical appearance.

The affection can occur in the scalp, although somewhat rarely, where it produces spots similar to those on the face. The diagnosis can only be made clinically when spots are also present on the face,

FIG. 2.

Streptococcal pityriasis irritated by the use of cold cream.

which is commonly the case. Their ætiological affinity is then clear from their identical appearance and their similar cultural results. Sometimes the hair falls out, and there is then a surprising resemblance to ringworm, from which it can only be distinguished by the absence of the fungus and the presence of streptococci in large numbers.

The disease is common on the neck, usually commencing with an extensive eruption on the face which sends offshoots downwards. These extensions frequently exhibit one of the most characteristic features of the disease—namely, its tendency to be irritated by sunlight. The area of skin shaded by the chin is often partially or completely protected. Its relation to light, which was long ago pointed out by Rasch, has great practical importance, because many cases of so-called eczema solare, especially when it is confined to the face, are really chronic cases of pityriasis streptogenes which are irritated by the light and become eczematous every summer. Perhaps the hypersensitiveness to light is due to the fact that the formation of pigment is partly or entirely suspended in the affected parts.

The lesion is also irritated by other factors than light—thus by ordinary washing with soap, by most of the soft salves like cold cream, vaseline, and especially lanoline; further by many other remedies, notably tincture of iodine and mercury. Of internal remedies bromine, at any rate, and probably also iodine can aggravate the disease. Arsenic and quinine may also undoubtedly cause the lesion to flare up. (Fig. 2.)

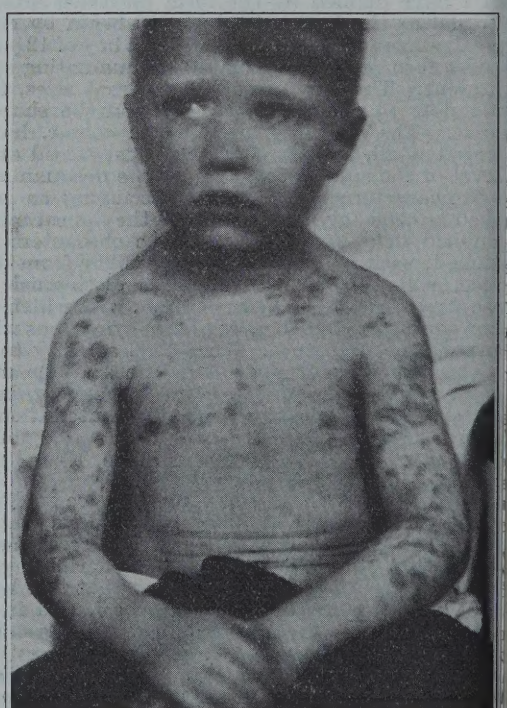
The eruption on the body is seldom the primary seat of the affection. I have, however, seen several cases who in addition to the typical eruption on the face also had a number of similar spots on the b and extremities. The cultural finding—masses streptococci—was, moreover, in conformity. W the disease occurs on the body it has, unlike seborrh eczema, a predilection for the lateral parts, a f which Sabouraud has previously pointed out. (Fig.

The complaint is rather more common on extremities, especially on the arms, where the sp however, are less typical in appearance than on face. When the disease is also present here, whic often the case, not only the similar cultural findi but also the clinical resemblance, which is undenia as soon as one thinks of the association, will disp their identical nature. The arms are particula affected in women.

On the hands the disease may greatly resem eczematous ringworm. As these cases are usu cured by antimycotic remedies they have no doub *ex jurantibus*—often been regarded as myco although the fungi were not found. But since it been shown that the genuine mycotic eczemas which the fungus can be detected do not harb streptococci while morphologically similar cases which the fungi cannot be found commonly do harb them in large numbers, we must certainly assume t streptococci are the cause of at least some of the c of ringworm-like eczema of the hands where the fun cannot be demonstrated. Fig. 4 illustrates suc case. The resemblance to mycotic eczema is obvio but besides the cultural result—numerous streptoco no fungus—the laminated streaky desquamat denotes its affinity with pityriasis streptoge (Fig. 4.)

The cases of pityriasis streptogenes which I h described so far had developed without anteced

FIG. 3.

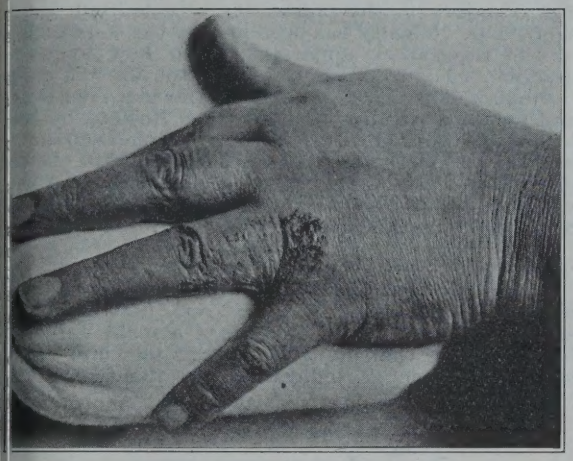


Streptococcal pityriasis involving face, body, and arms

impetigo. Those which arise after impetigo, howe exactly resemble the primary ones in appeara course, and bacteriological findings, and they thus be regarded as identical. Pityriasis streptog occurs after acute irritation of the skin as well as a impetigo—for example, following treatment scabies—and this clinical picture has long been re nised as due to streptococci by Sabouraud and

en termed by him "strepto-épidermite chronique." thyosis is frequently complicated by pityriasis eptogenes; but the spots cannot be recognised on previously scaly skin until they become eczematous. rther, there is much evidence in support of the w that the disease may complicate certain cases of ificial dermatitis following internal medication. us salvarsan and mercury dermatitis are remarkly frequently observed in patients suffering from

FIG. 4.



treptococcal pityriasis of the hand resembling eczematous ringworm.

yriasis streptogenes. Finally, the affection can doubtedly complicate true seborrhœal eczema, t the conditions in this case are so complex that ther investigation is needed.

Up to the present I have kept to the characteristic pearance, localisation, and bacteriological findings the individual elements in my attempt to establish yriasis streptogenes as an independent disease tinct from seborrhœal eczema. Although the ference between the clinical pictures of these two ections in all the points alluded to appears to me so eat that in itself it warrants us in drawing the tinction, I will, nevertheless, for the sake of completeness, mention certain discrepancies concerning its currence and course.

While true seborrhœal eczema in its typical forms curs principally in early childhood, at puberty, and the two following decades, pityriasis streptogenes ects chiefly school-children of from 6–14 years of e. But many cases also occur in adults, much ore commonly in women than in men. That, on the hole, it is a very common disease follows from the ures of the Polyclinic of the State Hospital in penhagen, where among 4700 patients in 1926 ffering from skin and venereal diseases there were 2 cases of pityriasis streptogenes. Of these 16 were n, 44 women, and 92 children. The corresponding ures for seborrhœal eczema were 72 men, 100 women, d 34 children. The relative distribution of the two eases according to sex and age is therefore rather ferent also.

An interesting point which comes specially into ominence because school-children are so often ected is the undoubted infectious nature of pityriasis reptogenes. Through the courtesy of various school ctors I have had the opportunity of seeing how hole classes can be attacked almost at the same time. he fairly common eruption on the arms in women is o often found in mothers of children with extensive yriasis streptogenes.

TREATMENT.

The treatment of the complaint is very successful. he rash frequently disappears on applying pure zinc tment if all external irritation, especially washing th soap, is avoided; but zinc ointment containing 1 to 2 per cent. coal-tar, or 2 per 1000 antrarobin, is the most certain remedy.

The clinical picture of pityriasis streptogenes which I have attempted to describe seems to me to be so typical, taken in connexion with the bacteriological finding, as to justify its separation as a clinical entity. The reason I have proposed the name pityriasis streptogenes in place of Sabouraud's "impetigo sicca" or Adamson's "chronic impetigo" is that the disease is secondary to impetigo in a small number of cases only, while the majority—all those cases classed by most people as seborrhœal eczema—occur primarily as a pityriasis and preserve this appearance in their future course.

Whether the streptococci found in pityriasis are impetigo streptococci whose virulence is merely diminished, or whether they are a special type, future serological research must decide. But, in any case, indications are that these streptococci are the cause of the disease. Even if the relationship to impetigo proves to be very close—as, for example, exists between impetigo and echthyma—we shall have just as much right to retain pityriasis streptogenes as a third form as we have to distinguish between the two clinical forms of streptococcal infection mentioned. From a purely clinical standpoint it is still further removed from impetigo and echthyma than these two diseases are from one another.

A METHOD FOR THE INDUCTION OF RESPIRATION IN THE NEW-BORN.

BY A. LOUISE McILROY, M.D., D.SC. GLASG.,
PROFESSOR OF OBSTETRICS AND GYNÆCOLOGY IN THE UNIVERSITY OF LONDON (ROYAL FREE HOSPITAL).

IT is only during the past few years that we have begun to recognise that vigorous and energetic methods of treatment of an infant born in a state of suspended animation are a mistake. These methods tend to increase the degree of shock and intracranial injury which occurs after a prolonged and difficult labour. Artificial respiration as practised by Schultz and others must have helped to some extent to maintain the stillbirth rate rather than to diminish it.

We should endeavour to render the postnatal conditions as nearly similar as possible to the antenatal, at least until the infant has become acclimatised to its new surroundings. The fœtus in the uterus lies in a water bath at an even temperature, it is protected from jolts and jars, and it receives a regular amount of oxygen and nutriment by means of the cord and placenta. Birth means a severe strain on the infant in some cases, and time is required to overcome the resulting shock. The infant is suddenly thrust into surroundings where the temperature is lower than that of the uterus. That the child loses a considerable amount of heat has been already demonstrated by a series of observations which I published in 1925.[1] When shock and loss of heat are combined with the ordinary drastic methods of artificial respiration it is not surprising that the results in some cases are disastrous. Warm baths may restore animation by the application of heat but they lead to rapid radiation from the skin on exposure consequent upon removal of the natural oily protection—i.e., the vernix caseosa. The method of placing the infant imme-

[1] Proceedings of the Royal Society of Medicine, 1925, vol. xviii.

diately after birth in a warmed blanket compares most favourably with a hot bath. Subsequent cleansing of the skin for several days with olive oil instead of soap and water prevents loss of heat and loss of weight. If the infant is suffering from cardiac shock there is nothing to be gained by trying to establish pulmonary respiration until the heart has begun to function again. Respiration occurs as the result of stimulation of the medulla by the reserve of CO_2 in the blood. If this reserve is lost by energetic movements as in artificial respiration pulmonary function fails to become established unless a fresh supply is forthcoming. Shock or white asphyxia in most cases follows undue intracranial pressure during birth or from interference with the placental circulation. Forceps applied to the extended head are liable to cause injury. This has been demonstrated by the research of Miss A. Baker in this unit. She found that if the head is not sufficiently flexed and the forceps applied obliquely there is danger of intracranial injury.

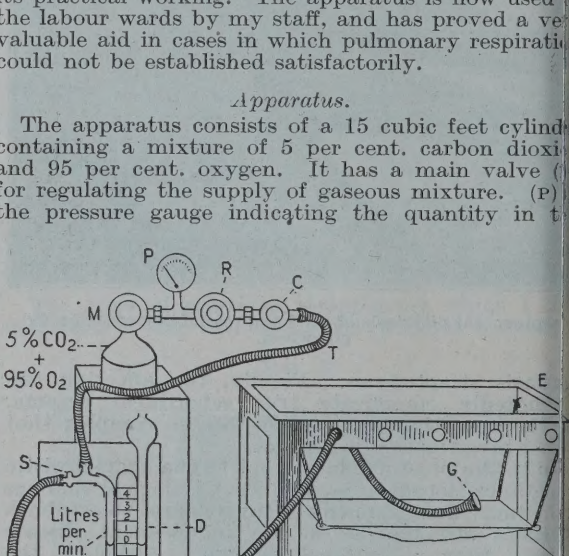
Treatment of White Asphyxia.

The most suitable treatment of an infant suffering from white asphyxia is as follows. The infant when born is wrapped in a warm towel or blanket. Its eyes are wiped and mucus is removed from the mouth and nose. When the cord is severed the child is transferred to a cot well warmed with blankets and hot-water bottles. If the air passages are still blocked by mucus a soft rubber catheter is used to suck it out. This catheter has a glass inlet and mouthpiece by means of which the mucus can be observed in the tube and its risk to the operator avoided. If the heart is only faintly beating stimulants, such as camphor ℥ii., or strychnine, are given hypodermically. Gentle massage of the heart is also employed. The mask of the apparatus about to be described is applied to the infant's face, and a gas mixture of 95 per cent. oxygen and 5 per cent. carbon dioxide is given at very low pressure. The mask is applied and withdrawn at the rate of about 16 times a minute. As soon as respiration is established the mask is left on the pillow near the mouth for about one minute. The cylinder is changed and pure oxygen is given for several minutes. The administration can be carried out in a cot with a curtain or in a special wood-and-glass "breathing box." The latter is not essential but it is desirable, as it ensures a warmed and even temperature (75° F. for the new-born). As soon as the infant breathes normally it is placed in its cot. It is subsequently cleaned with olive oil and dressed. Movements involving disturbance of the brain or spinal cord should be avoided. It is well to remember that infants born while the mother is under anæsthesia must take some time to revive as they themselves are under the influence of the drug. Also instead of precipitating delivery by means of forceps for fœtal distress it has been found by experience that the administration to the mother of cardiac stimulants at intervals during labour will do much to prevent the necessity for operative interference and the consequent shock during delivery. For some years I have been carrying out a series of observations upon the new-born, more especially with regard to the treatment of shock. I have given up the practice of artificial respiration except in those cases known as "blue asphyxia," in which there is cardiac function, but difficulty is experienced in starting pulmonary function. Gentle movements of the chest will do little harm, but these infants generally react quickly to the clearing out of the air passages. Although hot baths and artificial respiration have been given up in the cases of so-called "white asphyxia," it seemed to me that there was something wanting in more or less negative treatment. As the result of considerable research upon the cause of antenatal and neonatal deaths in the unit, we came to the conclusion that a supply of CO_2 to the infant would make up for its deficiency in the blood. It would also replace the old method of artificial respiration with its harmful effects in cases of intracranial injuries. I tried various devices but could not obtain a method free from ris Also, it was necessary to have a practical apparat at hand for all labour cases, and one which could worked by any member of the staff.

Prof. Yandell Henderson, of Yale, suggested th I should consult Prof. H. S. Raper, of Manchest and I am indebted to Prof. Raper for valuable advic and also to him and to Dr. Catherine Chisholm f showing me the method of administration of pu oxygen in the Manchester Babies' Hospital. T great difficulty in carrying out my ideas was to obta sufficient pressure of oxygen and CO_2 without t risk of injury to the pulmonary alveoli from diste sion. This difficulty has been met by the constructi of the respiratory apparatus I am now about describe. I am much indebted to Messrs. Siel Gorman and Co., Ltd., of London, for constructing and for the assistance offered by Mr. Rosling, of th technical staff, and also for many suggestions as its practical working. The apparatus is now used the labour wards by my staff, and has proved a ve valuable aid in cases in which pulmonary respirati could not be established satisfactorily.

Apparatus.

The apparatus consists of a 15 cubic feet cylind containing a mixture of 5 per cent. carbon dioxi and 95 per cent. oxygen. It has a main valve (for regulating the supply of gaseous mixture. (P) the pressure gauge indicating the quantity in t



cylinder. This communicates with a safety pressu apparatus consisting of an automatic reduci pressure valve (R) and a control valve (C) for regulati the supply. The gas passes by way of the tube and the manometer (D) through a long flexible tu to a small gas mask (G). At the point where the lo flexible tube leaves the manometer there is a safe valve (S). The tube passes into the breathing-b through one of the ventilation holes. The man meter, which has a water column, is a combined flo meter, low pressure gauge, and a safety valve. indicates the pressure of the passing gas and als by turning off valve (C), it can be utilised for t detection of respiration. The maximum pressure the passing gas is 8 inches of water. Above th pressure it escapes into the bulb. Under norm conditions the rate of the flow is adjusted to 2 litr per minutes. (E) is the breathing-box which insur warmth and the proper amount of oxygen a ventilation. (F) are hot-water bottles under t hammock on which the infant lies. In this way t maternal heat of the body is retained. The temper ture is about 75° F.

In order to treat a baby suffering from "whi asphyxia" the infant is placed in blankets in t hammock and the lid of the box left open. The g is turned on, and by means of the control (C) and t flow-meter the rate of flow is adjusted to 2 litres p minute. The mask is applied to the infant's fa about 16 times per minute, thereby exerting slig pressure in the lungs. If it is thought that respirati

stablished, no matter how faint, the flow-meter be made to register this in the following manner: ontrol valve (C) is shut off and the water column becomes level. If the mask is now applied ly and firmly to the face the slightest respiratory ement will be recorded on the manometer. When ration is established the mask is left near the th for one minute and the lid of the box closed. tubing (T) is disconnected at (C) and attached to xygen cylinder, and oxygen alone is given for a minutes at the rate of 2 litres per minute.

ie breathing-box is also employed for the treat- of babies in the wards who are "blue" because nperfect aeration of the lungs. The infant is n an hour's treatment at various intervals in the and pure oxygen is supplied. The temperature bout 65° F. is maintained by hot-water bottles. results are excellent and the mothers themselves rk on the improvement in colour when the infant ought back to the ward. In these cases the carbon de is supplied from the lungs themselves. This od is employed by Prof. Raper and Dr. Chisholm lder babies under treatment for disturbances of bolism. We have used it in some cases of cardiac re in infants some hours or days after birth.

conclusion, it must be borne in mind that the nistration of carbon dioxide and oxygen is not but was employed in ancient times by mouth-outh insufflation, and is still practised by some cal practitioners. The mixture is also of value ases of cardiac and respiratory failure under thesia.

NOTE ON THE TREATMENT OF JENSEN'S RAT SARCOMA BY ANTI-SERUM AND ADRENALIN.

BY THOMAS LUMSDEN, M.D. ABERD.,
AND
JOHN GOWER STEPHENS, M.B. SYDNEY, D.M.R. & E. CAMB.,
BEIT MEMORIAL RESEARCH FELLOW.

(From the Department of Experimental Pathology, Lister Institute, London.)

HEN antisera which have a specific affinity for r cells are applied to normal and to tumour cells red in vitro the former cells are undamaged, while atter are killed within a few minutes.[1] is fact suggests that appropriate antisera should eal agents for the treatment of tumours in living als, yet when such sera are injected into virulent ths without accessory treatment they are com-ively ineffective. This is in part due to the fact the cytolytic effects of the sera involve a reaction een colloidal systems and as such may be ted to have a comparatively slow reaction ity. Now it has already been shown [2] that ances injected into tumours pass very rapidly the general circulation,* and accordingly it nes imperative to localise the antiserum in the ur area. This had been previously accomplished mporary ligation of the base of the tumour,[2] or ie case of flank tumours by tying their main ry and inguinal blood-supply.[3] These methods, ely applicable to the invading new growths of have in the present instance been substituted by njection of adrenalin into and around the area treated. Not only does the adrenalin insulate the tumour and permit of localisation of the antiserum, but, as will be shown later, by arresting the blood-supply, and possibly in other ways, it has itself a curative influence.

Methods.

Flank tumours (Jensen's rat sarcoma = J.R.S.) of 6–8 days' growth were selected for treatment; at this stage these vary from about 1 in. to 1½ in. in length. The tumour area was epilated or shaved. Black and white or brown rats were used, since in these, inoculations of the virulent strain of J.R.S. employed give 100 per cent. of tumours, of which less than 5 per cent. regress spontaneously. Albino rats of all ages are entirely unsuitable, since they vary too much in susceptibility and untreated controls may show a percentage of regressions reaching as high as 20–40. Adult rats have a much greater power of producing immune bodies than very young rats; it is therefore important that the age of the rats should be noted when interpreting the results obtained.

Adrenalin hydrochloride solution (1 in 1000) is diluted with 19 parts of normal saline, and of this dilution 1 c.cm. is injected around the margins of the tumour, beneath it, and above it. Some ten minutes later 1 to 1·5 c.cm. of anti-Jensen's-rat-sarcoma serum from a sheep (A.-J.R.S.) is injected very slowly and with little pressure into and around the tumour. This treatment is repeated daily as often as is judged necessary—i.e., until the sarcoma has ceased to enlarge and is surrounded by an inflammatory area. If too severe measures are employed the whole tumour may slough out and no immunity follow. In some instances the adrenalin was mixed directly with the serum in the proportion 1 to 20, and this was injected into different portions of the growth at frequent intervals (15 to 30 minutes) till the whole tumour was saturated. By way of control adrenalin alone diluted with either normal serum or saline solution was employed.

Experimental Results.

The results of all the experiments are shown in the following table. It is practically certain that if adult rats alone had been employed these figures would have appeared much more satisfactory.

Reagent applied.	Results.		Total treated.	Per-centage of cures.
	Cured and immune.	Failed.		
Antiserum and adrenalin	29	31	60	48·3
Adrenalin alone.. ..	6	24	30	20

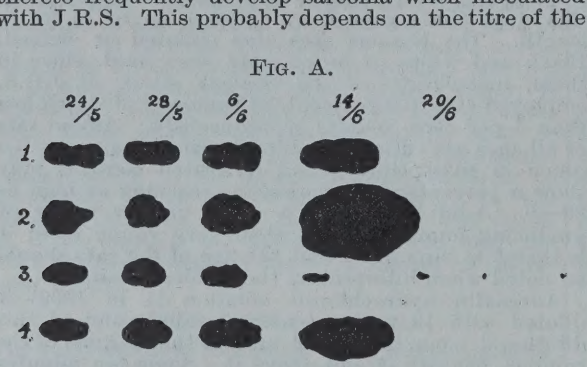
In the most successful of the experiments (illustrated in Figs. A, B, and C) of six rats treated with antiserum and adrenalin five were cured and immune, while of six control rats treated with adrenalin diluted with normal sheep serum only three rats were cured. In this experiment adult rats were dealt with. Where very young rats were employed the results were sometimes poor; thus in the least successful batch of five rats treated with antiserum and adrenalin only one was cured. This emphasises the observation that the production of immune bodies is essential for cure, since it is known that young rats have much less power of acquiring immunity than adults.

In 22 mice bearing a mouse cancer (M.63) of the axilla similar treatment was tried; the results were much less satisfactory. Often (in 12 mice) the tumour was entirely destroyed, leaving a large gangrenous area; this either sloughed away completely, no immunity resulting, or absorption of toxic matter from the degenerating area caused the death of the animal. In only two mice out of the 22 regression took place satisfactorily, and a test inoculation later proved these two mice immune. It appears that mice, like very young rats, have very little natural resistance and still less power of producing an acquired specific immunity.

[1] T. Lumsden: THE LANCET, 1925, i., 383.
[2] Lumsden: THE LANCET, 1925, ii., 539.
* striking confirmation of this fact is obtained if some ot soluble in blood—e.g., paraffin oil or benzol—is inocu- into a tumour; within a few seconds death ensues from lary embolism. A similar result follows the injection of cm. of air into a large implanted tumour. When the on is made into the normal subcutaneous tissues no such ensues.
[3] Lumsden: THE LANCET, 1927, i., 116.

It may be added that, confirming an observation previously reported,[3] rats which had been rendered immune to J.R.S. by cure of an existing sarcoma of the flank, were found to be immune also to the rat carcinoma R. IX. The converse does not hold; rats cured of R. IX. tumours and consequently immune thereto frequently develop sarcoma when inoculated with J.R.S. This probably depends on the titre of the

FIG. A.



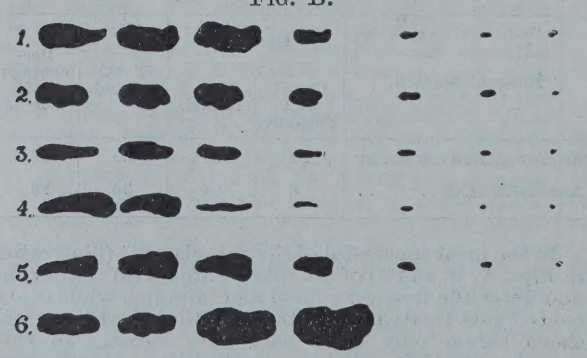
Tumours treated with adrenalin and normal sheep serum.

antimalignant bodies present, since J.R.S. is the more virulent of the two tumours.

Discussion.

The results obtained confirm the view already stated [2] [3] that if by inoculation of antiserum a rat sarcoma (J.R.S.) can be made to regress an active immunity is produced in the animal, which prevents recurrence and is of long duration. While injection of antiserum may be the best means yet found of inducing immunity it is not the only method of doing so. In a series of 13 adult rats 1 c.cm. of 0·2 per cent.

FIG. B.



Tumours treated with adrenalin and anti-J.R.S. serum from a sheep.

formol was repeatedly inoculated into the tumour; in eight of these rats regression of the growth resulted and the rats were here also found to be immune when test inoculated. Similar results have followed (as shown above) treatment of J.R.S. tumours with adrenalin alone. In nine animals the adrenalin was followed after a few minutes by injection of 1–2 c.cm. of distilled water; in four of these the tumours regressed and the rats were thereafter immune. Distilled water was employed because its lethal effects when applied to cultured tumour cells resemble more or less those produced by antiserum; it was also conceived that it might help to set free antigenic factors by causing rupture of the tumour cells.

It seems, then, that the aim we must keep before us is this: To find the simplest and most effective means of so damaging a tumour locally that its cells gradually die and become antigenic, and so induce a general active immunity. It matters little if the treatmen local, so long as the result is general. It is evident we may safely attain a much higher local concentra of any reagent in the tumour area by injectin locally than by instilling it into the general circulat where its effects would be exhibited in many part the body uselessly and perhaps harmfully.

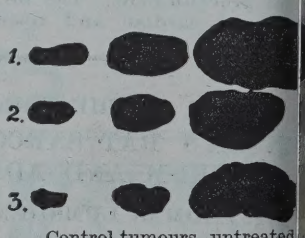
It may be well to tabulate here one or cautionary points referred to above or in prev papers:—

1. In comparing results, the age, breed, and co of the rats must be carefully considered. Pure w (albino) rats (two breeds were tried) should not used in experiments where J.R.S. is the tum experimented with.

2. Absorption into the general circulation of reagent injected into a tumour is very prone to oc and must be prevented as far as possible by ligatio adrenalin if the best results are to be obtained.

3. Frequently repeated small doses slowly inje are more effective than one large dose rapidly gi but since animals appear to become rapidly accli tised to any serum injected,[2] thorough treatment du the first 48 hours has advantages over a prolonged c repetition of small doses. On account of acclima tion it may also be of value to vary the antise administered—e.g., using for the cure of J.R.S anti-J.R.S. serum alternately with an anti-M serum, an anti-human cancer serum, or anti-guinea-pig sarcoma serum.

FIG. C.



Control tumours, untreated

4. The smaller the tumour the easier it is to cure. With the very virulent strain of J.R.S. we used, tumours of over 2 in. in length (8–10 days' growth) give poor results. There is little time available since if untreated the animals survive for a further 10–14 days, and even if treated any bodies formed are apt to be absorbed by the enor mass of tumour cells. Tumours under 1 in. in le (5–6 days) are very tractable except in the youngest rats (6–8 weeks old).

We are by no means clear that our present met are the best attainable; it is only by trying r different reagents that any conclusion on this can be come to.

Conclusions.

1. Sarcoma (J.R.S.) of the flank in rats of va ages can be caused to regress in at least 40–50 per of cases by injecting antiserum and adrenalin int around the tumour. After such regression the rat immune to reinoculations of this tumour and al inoculations of the rat-cancer R. IX. Cross-immu in the opposite direction is much less usual.

2. Adrenalin diluted with normal saline especially adrenalin diluted with normal heterol serum has a definitely curative effect. In 6 o 30 animals treated with adrenalin in saline regre with subsequent immunity resulted. When untr the tumours grew progressively in 98 per cent. of

3. Of 13 sarcomatous adult rats 8 were cure rendered immune by daily injections of 0·2 per formol into and around the tumour.

4. It appears that in all cases immuni evoked—damage to the tumour cells rendering antigenic—and that the induction of immunity essential factor in completing the cure and preve recurrence.

We are greatly indebted to Sir Charles M F.R.S., for permission to carry out this work a Lister Institute, and to Miss A. C. Kohn-Speyer, for much help, especially in keeping records o results. One of us (T. L.) has to thank the B Empire Cancer Campaign for a whole-time gra

ON THE
PARATIVE LABILITY OF ANTISERA CYTOTOXIC TO CANCER CELLS.

BY ALICE C. KOHN-SPEYER, B.A. OXF.

the Department of Experimental Pathology, Lister Institute.)

IE months ago while working with Dr. T. den on the effects of certain cytotoxic anti- n vitro, it was noticed that some of these were nger active if kept for more than a month, at 0° C., while others retained their toxicity least two years in the cold room.[1]

e former were also found to be inactivated, when recomplemented, after heating at 56° C. ew hours, while the latter retained their activity a much longer period of heating.

e experiments described below were undertaken tend these observations.

Methods.

e antisera tested were prepared by repeatedly lating fragments of tumours of various animals nimals of a heterologous species.

e following sera were chosen for investigation: nti-human-cancer serum made from a sheep. nti-Jensen's-rat-sarcoma serum made from a on each coverslip; to one of these cultures anti- serum was applied, the other was fed with normal serum as a control.

Rapid death of the actively migrating cells was taken as the index of toxicity of the antiserum.

Experimental Observations.

In all over 200 cultures were tested. The results obtained with the three antisera dealt with are set out in the following table:—

Anti-human cancer.		Anti-Jensen's rat sarcoma.		Anti-mouse cancer (M.63).	
Serum applied.	Cytolysis of M.63 cells.	Serum applied.	Cytolysis of M.63 cells.	Serum applied.	Cytolysis of M.63 cells.
	After—		After—		After—
Sample 1	5 hrs.	Sample 1	21½ hrs.	Sample 1	24 hrs.†
,, 2	6½ ,,	,, 2	20 ,,	,, 2	24 ,, †
,, 3	5 ,,	,, 3*	26 ,,	,, 3	49 ,, †
,, 4	5 ,,	,, 4	23½ ,,	,, 4	69 ,, †

* At 53° C. † Not tested later.

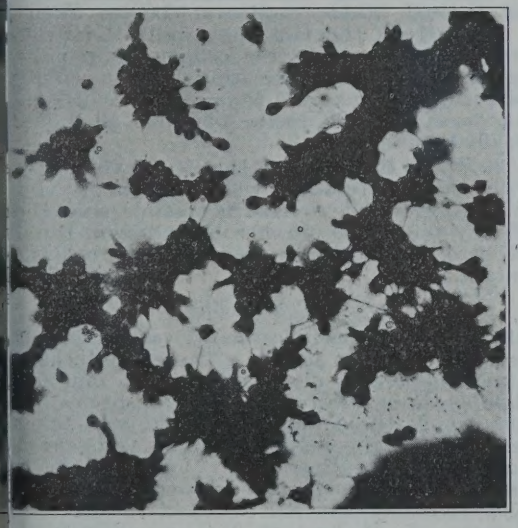
This table shows the longest period of heating at 56° C., which did not completely inactivate the particular antiserum tested; if the sera were heated beyond these periods no cytolysis occurred. The values for Anti-M.63 rabbit serum do not show an end-point, since no samples were tested after heating for more than 69 hours, at which period the antiserum was still effective. The results may be summarised as follows:—

Anti-Human Cancer Serum.—Heating for 6–7 hours at 56° C. completely destroys its cytolytic action on M.63, even in the presence of fresh complement. After 28 days at 0° C., or about six days at laboratory temperature (18° C.) the cytolytic action has similarly disappeared.

Anti-Jensen's Rat Sarcoma Serum.—This, when recomplemented, no longer retains its cytolytic action on M.63 cells after 21–24 hours at 56° C.

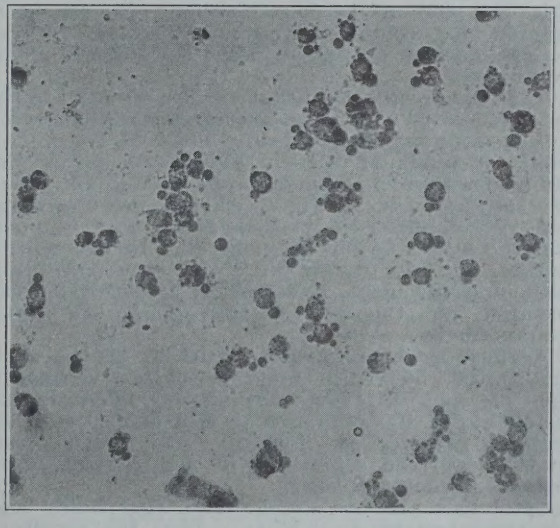
Anti-Mouse-Cancer (M.63) Serum.—This still kills M.63 cells by rapid cytolysis, when recomplemented, after 69 hours at 56° C. Keeping for over two years at 0° C. does not destroy its cytolytic effect on M.63 cells if complement is added.

FIG. 1.



e of mouse cancer (M.63) to which heated anti-mouse er serum had been applied without the addition of comple- t. The cancer cells are very markedly clumped, but are dead, and are beginning to migrate out again. (Iron matoxylin and Sudan.)

FIG. 2.



Control culture of M.63 in separate drop on the same cover- slip, stained coincidently with Fig. 1, showing the effect of heated anti-mouse cancer serum plus complement. Complete chromatolysis has occurred, the nuclei do not stain with hæmatoxylin, and death has occured too rapidly for agglutina- tion to take place.

. (3) Anti-mouse-carcinoma serum (M.63 of mperial Cancer Research Fund) made from a t.

e freshly prepared sera were run into short lary tubes and heated in a water-bath at 56° C. s were taken out singly and tested at hourly alf-hourly intervals. Similar samples were at 0° C. and tested every two or three days.

ce the cytolytic effects of antisera only take in the presence of complement, an equal part sh rat serum was added to all heated antisera.

e sera were tested on cancer cells actively migrat- ut of tissue cultures of mouse cancer (M.63) and n's rat sarcoma (J.R.S.) grown in pure rat serum. cultures in separate drops of serum were grown

[1] T. Lumsden: THE LANCET, 1926, ii., 112.

Discussion.

Although the results reported are sufficiently definite to demonstrate a marked difference of lability between the various antisera examined, the actual periods given in hours above must not be considered as absolutely fixed, since the following variable points must be taken into consideration: (1) The activity of the culture—age, vigour, number of migrating cells, &c. (2) The strength of the antiserum; this varies with the animal inoculated, the site and the number of injections, the length of time after the last injection, the length of time the serum is kept before heating. (3) The strength of the complement; this depends on the animal used, its freshness, and the actual dilution employed.

These factors were all considered in the above experiments and kept as constant as possible.

The complement question presented considerable difficulties. Guinea-pig serum could not be used as it is frequently toxic to mouse and rat tissues. Mouse serum was also discarded as it was found to be weaker and far more variable than rat serum in the amount of complement it contained. In order to give as little variation in the complement as possible, an equal part of fresh rat serum was always added to the antiserum in the above experiments, and the control culture was re-fed with the same rat serum alone.

It was noticed that addition of fresh complement was not needed even with heated antisera, if these were applied to cultures only 24 hours old, and which had been propagated in fresh rat serum, indicating that complement is still active after 24 hours in the incubator at 37° C. This observation is noteworthy, since if it were not taken into account, the erroneous opinion that complement is not necessary for the cytolytic action of sera on tissue culture cells might be formed.

That the presence of complement is essential to the cytolytic action of antisera on cancer cells is illustrated by the accompanying figures. These represent two similar cultures of M.63 in separate drops on the same coverslip, to which the same heated antiserum has been applied. In Fig. 2, where complement was added, complete chromatolysis has taken place and the nuclei do not stain at all. In the control culture, Fig. 1, treated with the same antiserum without complement, very marked agglutination has occurred, but the cells are alive, and the nuclei stain normally.

Agglutinins were found to exist in all the antisera tested, but when rapid cytolysis occurred in the presence of complement, migration ceased instantly and the cells died in situ almost as if an ordinary fixative—e.g., formalin—had been applied. In this case the agglutinins, though present, were unable to clump the cells.

Cytolysins are less stable than agglutinins and are more variable in lability. Thus the cytolysin of anti-human-breast-cancer serum is about four times as heat labile when tested on M.63 cells as the cytolysins of anti-Jensen's-rat-sarcoma serum, both sera being obtained from sheep.

The simplest explanation of this difference in lability is that an anti-cancer serum contains two cytolytic factors: (*a*) One that is specifically antimalignant, although not specific to any particular tumour. This factor is labile. (*b*) One that is antagonistice to the group of animals from which the antigenic tumour was taken. This factor is relatively stable.

It is by antibodies of type (*a*) = antimalignant, that antihuman breast cancer serum kills M.63, and by antibodies of type (*b*) = antispecies, that heated anti-M.63 serum acts on M.63, while fresh anti-M.63 serum is lethal to M.63 by virtue of containing both factors.

The following points observed during this investigation confirm this view. In an antiserum tested on M.63, wherever mouse-rat-group antibodies are present stable cytolysins are also present, and, on the other hand, only labile cytolysins are present when anti-mouse-rat-bodies are absent. Thus any antiserum m by using a rat or mouse tumour as an antigen conta a stable element toxic to M.63. Any antiser made from any tumour of another species—e guinea-pig or man—kills M.63 by means of a bodies which are comparatively labile. The existe of an antibody to M.63 in a "hyperimmune" J.R rat [2] is perhaps the best proof of the existence o separate antimalignant factor. This serum is pu antimalignant, it has no effect whatever on nor mouse tissues, and its cytolysin is more labile t that of any other antiserum tested. Simila in anti-human-cancer serum (no anti-rat-mo group bodies being present), antimalignant bo alone act on the M.63 cells, and the effect is absolu specific to cancer cells. If this antiserum is appl to a culture of mouse cancer, heart and kidn the cancer cells are picked out and killed rapi while the heart and kidney cells are left q undamaged.

As might be expected, the antispecies bodies most stable against tumours of the particular spe from which the antigen was derived, but they stable, although to a less degree, against the tumo of closely-related species—e.g., mouse or rat. T anti-J.R.S. bodies are more stable on J.R.S. than M.63 and vice versa. In an experiment to demonstr this, it was found that while anti-M.63 serum killed M.63 after 49 hours, it no longer killed J.R after 42 hours, and on the other hand, while a J.R.S. serum still killed J.R.S. after 27 hours more, it no longer killed M.63 after 24 hours.

A confirmation that anti-M.63 serum is toxi M.63 both through labile antimalignant antibo and through stable species antibodies when fr is supplied by the fact that while the fresh a serum kills mouse cancer cells more rapidly t normal tissues, it loses this specific affinity malignant cells if heated for some hours or kept s months in the cold room, and kills all mouse c equally rapidly.

The above facts suggest that to get the best res when treating tumours with antisera in vivo, sera used should be as fresh as possible, since the m recently the antiserum has been drawn, the hig the titre of specifically antimalignant bodies it contain.

Conclusions.

1. The cytolysins investigated vary in heat labi according to their nature. Those specifically t to malignant cells alone are at least four times labile as those directed against the species or gr from which the antigenic tumour was taken. From testing the heat lability of anti-cancer s it appears that heating at 56° C. for 6–7 hours dest the specific antimalignant element, while the a species element may still be effective after 69 h or more. 3. If kept at 0° C. complement is effective after about three weeks, the antimalign element after four weeks, while the antispe element is still active after two years or more.

In conclusion, I should like to thank Dr. T. Lums for his help and criticism during the progress of investigation, and the British Empire Cancer Camp for their grant to me.

Clinical and Laboratory Notes.

A NOTE ON THE REVENTIVE TREATMENT OF SYPHILIS.

BY H. D. LIVINGSTONE SPENCE, M.D., M.CH. Q.U. ONT.

'WENTY years ago great interest was aroused by chnikoff's statement in the course of his Harben ures that the inunction of a mercurial ointment, irst proposed by Behrman of Nürnberg, prevented sequent clinical manifestations of lues if performed he site of inoculation within 18 hours. Except for human subject his investigations had been ducted with anthropoids, chimpanzees being the y animals then readily inoculable with syphilis, their availability determining the number of his eriments. Experience has since confirmed the ability of mercurial ointment if correctly applied hin an hour of accidental exposure during operative k, but its use as long as 18 hours after the event st be regarded as of very speculative utility.

tubbing mercurial ointment into an accidentally cted finger is, however, on quite a different footing n the application of the same substance at the site sites of possible contamination during coitus. A longed inunction into the glans penis is rightly arded as an almost intolerable procedure, and even ere properly performed no absolute protection alts, since primaries may still develop upon reated parts of the genitalia or farther afield lough bites or lascivious kissing. The method, too, napplicable to females. Duly impressive statistics re been published purporting to show the effective- s of the "Dreadnought" ointment in preventing s, but the writer's observations in war camps ommodating upwards of 40,000 men, where records e methodically kept, were intensely disappointing. seemed that the man who used the stuff fared no ter and no worse than the unbeliever who just relied n plenty of honest soap and water, coupled perhaps h the ancient custom of washing the parts in ded urine.

Let us now consider the case of the person who sents himself a day or two after exposure, when phylaxis can only mean arsenical medication. ven acceptable evidence of actual contact no tification exists for delaying treatment until the roborative appearance of a primary sore dismisses y possibility of administering a coup de grâce; for, a true analogy obtains between human and rabbit ections, the disease is already systemic when the ancre appears. In a little more than two years I ve given anticipatory treatment to 11 private ients, being satisfied that they had in fact been posed. Insistence upon valid evidence of such posure not merely rules out the large class of psycho- hs and syphilophobes, but provides good ground in y for any action taken—a point of obvious import- ce. The following brief notes sufficiently illustrate e sort of history these individuals furnish and the ctical certainty of contamination.

May, 1925: A male patient with a small sore containing rochætes admitted connexion with his consort upon urning from abroad two days previously, the character of lesion being then unsuspected. The woman accepted ventive treatment.

September, 1925: A male patient upon the day following posure learned that a friend had acquired syphilis from same woman a fortnight before. A prophylactic injection s given after the friend had been located and the diagnosis nfirmed.

July, 1926: A male patient upon exposure noticed quieting symptoms in his partner, including an early h, and without disclosing his fears persuaded her to company him for advice concerning a "chill." Upon presentations she accepted routine treatment, the man eiving a prophylactic injection.

In each instance a careful history is accompanied by a complete physical examination, including the usual tests of the renal function, the circulatory apparatus, eyes, and reflexes. A sample of blood is then obtained for a Wassermann test, and finally 0·6 g. novarsenobenzol is administered intravenously. The Wassermann test is again performed at the end of the sixth and tenth weeks. No lesion has appeared in any of these patients, and serum tests have been uniformly negative, suggesting that novarsenobenzol used alone and in this moderate dosage is protective when given within a day or two after exposure.

London.

TWO CASES OF FUNCTIONAL PARALYSIS OF THE LEGS FOLLOWING LABOUR.

BY M. SALMOND, M.D., B.S. LOND.,
THIRD ASSISTANT, OBSTETRICAL AND GYNÆCOLOGICAL UNIT, ROYAL FREE HOSPITAL, LONDON.

THE two following cases are worth recording because functional paralysis is an uncommon complication after labour. They both occurred during the last six months in the practice of the Obstetrical Unit of the Royal Free Hospital.

CASE 1.—A 1-para, aged 24, had a spontaneous normal delivery of her second child. Her condition was satisfactory until the tenth day when she got up. She was then unable to use her legs or stand and there was weakness of the right arm and hand. On examination the cranial nerves and fundi were normal. The abdominal reflexes were present, the knee-jerks increased, and the plantar responses normal. Sensation was unimpaired. There was loss of power in the right arm and hand and in both legs. The patient was not of a nervous or emotional type. The condition responded rapidly to massage and diathermy and the patient was able to leave hospital in less than a week's time. She was walking, but not perfectly. Further treatment was to be continued as an out-patient.

CASE 2.—A primigravida had a very long labour, the membranes rupturing early in the first stage. She had poor pains in the first stage but complained bitterly of them. She was very difficult to control and was given opoidine and hyoscine hydrobromide. She complained during labour of severe pain in her left leg and said that it was paralysed, though movements of the limb were unimpaired. The presentation was vertex, right occipito-posterior, manual rotation was performed, and a stillborn child was eventually delivered by forceps. The patient was an extremely nervous and emotional woman. The puerperium was uneventful except that she said that her leg still felt numb. On getting up on the tenth day she was seen to drag her left leg behind her when she walked. On examination the nervous system was normal except for a slight increase in the force of the knee-jerks. She was treated by massage and diathermy and discharged in ten days walking well and without pain in the leg.

The two cases form an interesting contrast. In the first the paralysis occurred in a normal placid type of patient after a rapid easy delivery. The second patient was a highly nervous neurotic woman. Labour was prolonged and difficult.

I am indebted to Prof. Louise McIlroy and Dr. W. M. Gray for permission to publish these cases.

RAMSGATE HOSPITAL.—Dame Janet Stancomb-Willis has provided a home for the nursing staff at Ramsgate Hospital at a cost of £10,000.

THE NEW BETHLEM.—The plans of the new Bethlem Hospital on the Monks Orchard Estate have been completed and approved by the Governors. At the request of the Charity Commissioners the Board of Control are satisfying themselves as to the adequacy of the scheme, both as to building and cost. The total income of the hospital last year was £52,614, the expenditure exceeding it by £175. A total of 516 patients were treated (221 males and 295 females). Three hundred and eight persons were discharged; the percentage of recoveries on direct admissions was 56·38. Two hundred and ninety-eight persons were admitted, of whom 112 were paying patients. There were 27 deaths.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT EDINBURGH.

(*Continued from p. 337.*)

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

WEDNESDAY, JULY 20TH.

THE RELATION OF PREGNANCY TO GENERAL DISEASES.

AT the first meeting of this Section, under the presidency of Dr. J. H. FERGUSON (Edinburgh), Prof. MUNRO KERR (Glasgow) opened a discussion on this subject and spoke of

Heart Disease.

He pointed out that it was not yet decided whether the left ventricle hypertrophied during pregnancy or whether the extra effort was brought about by its latent reserve. Recent studies by Jensen and Norgaard showed that cardiac hypertrophy was normal and was associated with dilatation in 60 per cent. of pregnant women. In late pregnancy the heart was displaced upwards and backwards. Normally there was no change in blood pressure, but variations readily occurred from metabolic disturbances. Next to examination of the urine, estimation of the blood pressure was the most important detail in antenatal examination. The pulse-rate was very easily disturbed in the later weeks, and the increase in body-weight, blood volume, and cardiac output all played a part in producing variations. Some of the functional disturbances encountered were due to pressure from the uterus; others were caused by disturbed innervation, altered metabolism, and glandular activities.

In the real organic cases there was general agreement that it was the condition of the heart muscle that determined the gravity of the case, but the problem was complicated by the insidious metabolic and glandular variations of pregnancy. Coöperation between physician and obstetrician had resulted in a general consensus of opinion on the distress signals and treatment. Figures from the Royal Maternity Hospital at Glasgow showed a mortality of 22 per cent.; the average figure lay between 15 per cent. and 25 per cent. All the fatal cases in Glasgow suffered from mitral disease.

Danger Signals.—It was most important that cardiac cases should be sent into hospital in time to give medical remedies a fair trial. All evidence indicated a general tendency to earlier and more pronounced decompensation with each succeeding pregnancy. A history of unsatisfactory or easily unbalanced compensation before the pregnancy gave cause for special anxiety. General evidences of failing circulation were more important indications of danger than occasional cardiac irregularity. The prognosis became grave when cyanosis, œdema, albuminuria, and continuous crepitation appeared. For such cases Prof. Kerr always tried medical treatment for a week or ten days before terminating pregnancy. Where the heart was enlarged and other organs markedly disturbed the pregnancy should be stopped as soon as possible. Aortic regurgitation was not very common in pregnant women, but if uncompensated was very serious, especially with a "Corrigan pulse." Operative treatment should not be too long delayed, as once decompensation developed it was generally impossible to arrest it. Prof. Kerr's experience of mitral regurgitation agreed with that of Lennie, that if the cardiac muscle were satisfactory the prognosis was good. Mitral stenosis was the most difficult to gauge and most often caused anxiety.

Treatment.—While in many cases the shortening of the second stage by forceps was all that was necessary, constant consultation between physician and obstetrician was required to determine the exact moment when operative interference was best indicated. The operative intervention was often the immediate cause of death, either through delay or through selection of the wrong method. Emptying the uterus was not a simple matter, and it was most important to choose the method which would cause the least shock. In the early months the cervix must be dilated, ar stretching a sphincter had a pronounced depressi effect on the heart. If it were done gradually by ten time was lost, and tents were difficult to introdu aseptically in a primipara. The operation of electi was vaginal hysterotomy. During the later wee introduction of bougies was difficult in the primipa and there was no guarantee against one or two day delay. The speaker was convinced that Cæsare section would prove the accepted treatment of t future. The mortality figures in Lennie's series 17 cases was 11 per cent., although including some the worst cases, while the death-rate from the boug method was 44 per cent. Moreover, this operati allowed sterilisation and even hysterectomy in cas where it seemed advisable to stop the menstrual flo without interfering with the ovaries. Even whe labour came on spontaneously there was an advanta in Cæsarean delivery, as the shock of dragging a chi through the undilated vagina of a primipara was grav The anæsthetic was a factor of considerable importanc

The Puerperium.—Quite often heart failure set three or four days after the labour had been succes fully tided over. Two factors probably played a pa in this: degeneration of the hypertrophied muscl fibres and absorption from the decidual débri Autopsy often showed evidences of a superimpos acute endocarditis. The puerperium therefo demanded particular care and attention.

Tuberculosis in Pregnancy.

Dr. E. RIST (Paris) said that the belief of Hipp crates, that pregnancy was a cure for consumptio had not been fully eradicated; some medical m still believed that consumptive women could be children without paying heavily. Since we h learned to distinguish between the infection and t disease we had ceased to rely on general symptom The most fundamental signs were the demonstrati of a lesion by X rays and the presence of bacilli the sputum. While many cases of tuberculosis we overlooked it was by no means uncommon for oth morbid conditions—some harmless, some serious— be treated as tuberculosis. It was this diagnost doubt that accounted for the differences of opinion to the effect of pregnancy. Statistics based reliable diagnostic criteria invariably showed th pregnancy led to an aggravation of symptoms, to t extension of existing lesions, to the production fresh ones, and to the flaring up of those quiescer The few exceptions were women with very mi fibrotic tuberculosis. The speaker's figures show that 89 per cent. of his phthisical patients were ma worse by pregnancy, and 58 per cent. died after o or two years. Most commonly the patient had be in good health before pregnancy, and consumpti symptoms appeared during pregnancy or the pue perium. There was no better criterion of cure in treated tuberculous woman than the ability to be a child without mishap. It had been found th 20 per cent. or more of pregnant women lost the capacity of giving a positive skin reaction to tubercul and only recovered it some time after parturitio Pregnancy seemed to be one of the causes whi diminished the specific allergic resistance to tube culosis, but the reason was far from clear. Dr. Couland, of Paris, had shown that abortion ar castration had the same effect, while the advent puberty or the menopause and of each pre-menstru phase might be accompanied by a marked failing the skin reaction. The effect of menstruation tuberculous symptoms was well known, and a hig proportion of cases occurring in later life began at th menopause, while Couland had collected a number cases where it followed double ovariotomy. In h opinion the hyperactivity of the thyroid was th connecting link. People with an abnormally lo thyroid action rarely got consumption, and then on in a mild form.

Treatment.—There had been considerable oppositi to operative interference. If abortion were accepte as the correct measure it would frequently be don

ıjustifiably or unnecessarily, nor had it been proved ficient in arresting the course of the disease. It ight be quite as unfavourable as a confinement. rtificial pneumothorax should be tried wherever it as possible; it had been proved to interfere in no ay with the favourable course of pregnancy and bour, and so had the advantage of saving the child's e in many cases. Dr. Rist then gave the figures of study of 58 women for whom pneumothorax had en tried. 27·5 per cent. were successful, but among omen so treated before pregnancy started the sults were much more encouraging. The older the neumothorax when conception occurred the better. a woman who had been treated in this way had en clinically well for two years there was no reason hy she should not become pregnant; but the llapse should be maintained during the first trial id for at least six months after confinement, and e should not nurse the baby.

Prof. F. J. BROWNE (London), speaking of

Venereal Diseases in Pregnancy,

alt first with syphilis. He laid special stress upon ethods of diagnosis and emphasised the great value an examination of the ovum in the diagnosis of philis in the mother. The mother of a syphilitic ild was always herself syphilitic, although a philitic mother might occasionally give birth to an fant in which no sign of syphilis could be detected. e pointed out that it was essential to give treatment each successive pregnancy, whether the patient peared to be cured or not. He next dealt with me of the difficulties in diagnosis and treatment of norrhœa and with the value of a negative smear. The following principles were laid down as essential r the proper management of cases of syphilis and norrhœa in pregnancy.

1. A routine Wassermann test should be carried out in antenatal clinics.
2. The treatment clinic should be in the maternity spital and not in an ordinary V.D. centre.
3. The treatment was best carried out by women doctors.
4. Beds should be provided in every maternity hospital cases of venereal disease. They were necessary for tients with acute or complicated gonorrhœa, for those o lived too far away to attend regularly for treatment, and those who suffered from venereal disease along with other mplications of pregnancy requiring indoor care—e.g., uminuria or heart disease. These beds should not be elled "V.D.," but should be classified and referred to as ntenatal," and be a part of the antenatal department.
5. A pathologist should be available who is able to amine the ovum for evidence of syphilis.
6. A list of infants believed or suspected to be suffering m syphilis should be sent monthly, or oftener, to the ild welfare medical officer, so that he can follow them up.
7. A follow-up nurse was essential to hunt up patients o failed to attend regularly for treatment.
8. There should be the closest touch between the maternity D. clinic and the ordinary V.D. treatment centre in order at cases may be referred for postnatal treatment and at the husband may also be treated effectively.

General Discussion.

Dr. GIBBON FITZGIBBON related a series of 22 cardiac ses which had occurred among a total of 13,000 con- nements during his mastership of the Rotunda ospital. They were all cases of failure of compensa- on and showed a mortality of 22·7 per cent. From review of these he divided such cases into three oups for prognosis. The first included those in hom decompensation only occurred as a result of bour and in whom prognosis was good. The second oup was that in which decompensation occurred ring pregnancy; if treated early and especially in young primipara the prognosis was good, but was id in the third group where decompensation was glected until the onset of labour. The prognosis r the infant was good when the mother was treated. ecompensation did not tend to develop until the cond half of pregnancy, but its onset was found ogressively earlier as the number of pregnancies and ie age of the patient increased. Over 75 per cent. compensated primigravidæ would go to term; ne-third of them developed failure in labour, but ey delivered themselves of living infants and recovered. Only 50 per cent. of multigravidæ would go to term, and rather more of them than of primiparæ showed heart failure in labour. Compensation was more difficult to re-establish during pregnancy in a multipara than in a primipara, and there was a marked tendency to relapse during labour. After treatment the pregnancy almost always ended at the 36th or 37th week. Cardiac lesions tended to produce abortion and diminish the incidence of pregnancy. Women who had shown no signs of heart failure might continue through labour, with especial care during the last eight weeks in a primipara and 16 weeks in a multipara. The latter would probably be best delivered by section at the 36th week if symptoms of failure had appeared, and should be sterilised. If symptoms appeared before the 30th week she should be delivered as soon as possible, as it was most unlikely that pregnancy would continue until a date of viability. Labour during decompensation was easy and rapid. In a subsequent pregnancy the case of decompensation in labour should be kept at rest from the 24th week, and pregnancy should be ended at the 36th week by section with sterilisation. The case of decompensation during pregnancy should never be allowed to continue with another pregnancy. Induction of labour had no place in the treatment of decompensation, and at other times would be better replaced by section and sterilisation.

Sir EWEN MACLEAN quoted the opinions of those who had had large experience of tuberculosis and pregnancy—Dr. D. A. Powell, tuberculosis physician to the Welsh National Memorial Association, and Dr. A. Brownlee, of the Glan Ely Tuberculosis Hospital. Their attitude was less pessimistic than that of Dr. Rist. He agreed that many diagnostic mistakes were made in recorded cases. The supposed improvement during pregnancy might be due to the altered metabolism, giving an appearance of better health. It might also be partly due to the pressure of the uterus on the diaphragm, acting in the same way as phrenicotomy. Dr. Powell said that tuberculous women need not avoid marriage, but no risk of pregnancy should be incurred until three years after the disappearance of signs and symptoms. If pregnancy occurred during the course of the disease it might be allowed to go on if there was no infection of the larynx or, in surgical cases, of the hip or spine.

Prof. LOUISE MCILROY did not agree with Prof. Kerr's pessimistic outlook on cardiac cases. No other class of case had illustrated so well the value of antenatal work. She showed tables of 158 unselected cases, of whom 2 per cent. died. Rest was the keynote of the treatment; it was no use to flog the failing heart of a poor working woman with digitalis and other stimulants. The obstetrician was useless in the diagnosis of heart conditions; the physician must be consulted. At the Royal Free Hospital an electrocardiogram and a weekly antenatal cardiac clinic had been instituted. The majority of cases seen were mitral; next in number came the "toxic" heart. Only when every form of medical treatment had been tried in vain should pregnancy be terminated. If abortion was done once it would have to be done many times; the patients would come back again and again. It was a rule at this hospital never to do Cæsarean section unless the patient were in labour, and this had greatly reduced the number. Many apparently hopeless cases would go through labour easily and normally. Many young women might be able after some years of treatment and care to have a child again without danger; sterilisation, therefore, was not desirable, and such cases were supplied with a Dutch cap contraceptive pessary on leaving hospital. The speaker did not approve of subtotal hysterectomy, as the absence of the menstrual outlet produced bad effects on the blood pressure. She laid stress on the break in the continuity of treatment of the tuberculous mother. The sanatorium would not keep patients after the seventh month and they were often sent out to a poor home under the worst possible conditions. This was one of the reasons for relapse after the confinement, and public health authorities should

be forced to provide an institutional home for them. Continuity of treatment was also of great importance in venereal diseases. Cases at the Royal Free were put in a special ward and visited weekly by the V.D. specialist and sent back to the V.D. department after delivery.

Mrs. M. MACNICOL (Edinburgh) urged that syphilis and gonorrhœa were quite different problems and that it was time to drop the obsolete common term "venereal disease." Syphilis could be accurately diagnosed and fully and satisfactorily treated; in gonorrhœa the reverse was the case. Among the last 150 cases sent to her with persistent discharge, all clinically chronic gonorrhœa, not one had shown the gonococcus at the first taking of a film. It was most important to impress on all syphilitic patients that they must report for treatment when next they became pregnant. The usual course should then be given whether there were indications for it or not. Antisyphilitic treatment was often justifiable and successful in cases of repeated miscarriage and still-birth, even if the Wassermann were negative. There had been two cases of sudden death at the second intravenous injection of arsenic after confinement, so that the speaker now made it a rule not to start treatment before the third month. The number of women suffering from purulent infective discharges during pregnancy was never realised before the establishment of antenatal centres. The cervix might be found bathed in pus, teeming with micro-organisms, even when no discharge was complained of. The discomfort and damage to health so caused could not be exaggerated. In-patient treatment was not possible or necessary; patients did well on bi- or tri-weekly cleansing. Acriflavine and gelatin pessaries were very useful and should be followed 12 hours later by lactic acid swabbing. One of the worst features of gonorrhœa was the sudden unexplained lighting up of a salpingitis or ovaritis after parturition. Usually, however, the puerperium of carefully treated cases was uneventful. Sometimes the condition could not be cleared up and a certain amount of purulent discharge, inflammation, and irritation subsisted. This was worse in the last week or ten days, when the head was in the pelvis. Therefore where there was erosion and profuse discharge the woman should be admitted during the last three weeks of pregnancy. The results of treatment became manifest after delivery, although in some cases a discharge persisted through lactation.

Dr. E. K. MACKENZIE (Tain), speaking from the experience of a rural practitioner in the Highlands, said that mitral stenosis in primiparæ and aortic incompetence in multiparæ had given him most trouble. The former had a strong tendency to cause distressing symptoms after the sixth month. He treated his cardiac cases by rest, not often easy to enforce, some modification of the usual flatulence-producing diet of the crofter, a morning dose of salts, and a weekly blue pill in the later months. He only gave digitalis if there was fibrillation of the auricle; it was best given in Guy's pill. It was surprising how well patients went on. He assisted labour with morphia, but found that hyoscine caused depression and mental distress, while pituitary extract was dangerous even when it would be helpful in other cases. When the head reached the perineum he administered light chloroform anæsthesia and helped delivery with gentle traction on the forceps. The most distressing feature of aortic cases was the mental disorder so often encountered; it included alienation from family and friends and abusive excitement, and was a potent factor in producing heart failure. Palliatives helped the patient to carry on, but abortion gave immediate mental relief with no memory of the excited phase. He induced labour before full term and used morphia and hyoscine, with pituitrin in repeated small doses.

Dr. R. H. PARAMORE (Rugby) suggested that the reason why the blood pressure was not raised in normal pregnancy was that the skull and limbs received a greater blood-supply; this explained the tendency to right heart failure. He advised hysterectomy if the Cæsarean operation were to be performed, because this removed from the kidneys the strain of dealing with the products of puerperal autolysis.

Prof. R. G. MCKERRON (Aberdeen) said that pregnancy with advanced heart disease was always a serious matter, and its treatment aroused much difference of opinion. Interruption of pregnancy in the early months was very seldom necessary.

Mr. D. LEES (Edinburgh) declared that the end result of gonorrhœal smears was not worth the paper it was written on. He mentioned the significance of leucodermia and melodermia in the neck as pathognomonic of syphilis and the value of a provocative injection of salvarsan three or four days before doing the Wassermann test. He urged continuity of treatment for venereal diseases and agreed that the term was undesirable as a large proportion of the patients did not suffer from disease venereally acquired. They should be handled in the gynæcological department. Syphilis rarely caused high blood pressure, but was not infrequently the source of heart lesions which responded well to antisyphilitic treatment.

The PRESIDENT recalled a case of double aortic and mitral lesions where the woman had had five children, illustrating the value of allowing old-standing cases a chance. A frequent cause of collapse after delivery was the accumulation of blood in the right heart; venesection would bring such patients back from the gate of death.

Prof. MUNRO KERR, replying, said that he agreed with the President about blood-letting and with Dr. Paramore about the value of hysterectomy, and admitted the importance of recognising the syphilitic heart. His cardiac cases were very grave ones only if had he included all patients his figures might be more like Prof. McIlroy's.

Dr. RIST, in reply, explained the experience on which he based his pessimistic attitude. He thought that if obstetricians followed up their tuberculous patients over long periods of years they would come to agree with him. They seldom saw the almost cataclysmic exacerbation when the patient returned to the physician. He did not think the effect of pregnancy on the lungs could be compared with that of phrenicotomy, as in the latter case the movements of the diaphragm were not only impaired but actually reversed.

THURSDAY, JULY 21ST.

At the second meeting, under the chairmanship of Dr. GIBBON FITZGIBBON, Prof. R. W. JOHNSTON (Edinburgh) opened a discussion on the

Hygiene of Menstruation in Adolescents.

On wise management early in the reproductive life, he said, often depended the happiness or misery of a woman's later years. The changes of puberty and adolescence concerned not only the reproductive organs but the girl's entire organism. Modern research had suggested that all the glands of internal secretion played a part in the development of the secondary sex characters, and so it was obvious that this period was a very critical one. Although the whole organism took part, the sex organs were the star performers, and Nature was concerned almost entirely with reproduction. If other functions were developed at the expense of this one Nature exacted a heavy penalty. During adolescence the reproductive organs called for an especially good supply of blood and nerve energy, and the extensive diversion of these to the muscles or the brain was probably responsible for many disorders of menstruation and reproduction.

Menstruation was a natural phenomenon, and the ideal to be aimed at was a natural life. In terms of civilisation that meant "moderation in all things." Too strenuous a life, too much physical or brain work, too much frivolity, and serious irregularity might do irreparable damage. Almost as dangerous, however, was the fostering of the idea in a girl's mind that she was a subject of very special physical delicacy in these periods. This attitude was a relic of the past, based

the mystery which until recently had enshrouded enstruation. The Jews to this day believed that it as a cathartic process and that a menstruating oman was in some way impure, to be forbidden a rt in ordinary social and religious life. From this veloped the belief that menstruation, especially at beginning, produced a delicacy which debarred the oman from active exercise or work. There was in is idea a certain amount of truth, but the unfortunate le of it was the implication that menstruation was thological—vide the expressions "unwell," or poorly," and the reticence surrounding the whole bject. The profession had to dispel the relics of is tradition. A sane outlook would do away with uch dysmenorrhœa, as did the exigencies of war rvice. Finally, girls should be taught the significance the menstrual function, better individually than in ass, and preferably by their own mothers. To allow em to acquire distorted or evil ideas haphazard was imperil their happiness.

School Life and Irregular Menstruation.

Dr. J. H. P. PATON (St. Andrews) stressed the portance of laying down a high level of general alth before puberty. This was secured nowadays regular school games. Although many girls could ay games during the period with advantage, he ought that the rule at St. Andrews, of stopping mes for the first three days and substituting walking ercise, was a good one. He exhibited tables to ustrate the incidence of dysmenorrhœa in this school, d showed that the percentage of total immunity as very high. 78 per cent. had no pain and 90 per nt. had no regular pain. Habits between periods re, he said, more important than habits during the riod itself.

On the subject of regularity his statistics proved at intermittent amenorrhœa was the rule up to 16. egular menstruation was rare at 13 and 14—only per cent. of the girls claimed it; at 16 the figure as better, 46 per cent., and at 17, 18, and 19 it rose 62 per cent. These figures were alarming, for if e common belief was true they indicated a persistent ficiency of ovarian secretion in a large proportion the mothers of the future. Many girls menstruated gularly in holidays and irregularly at school, and e reason was undoubtedly the long hours of con- uous mental and physical effort imposed by the odern school curriculum. He quoted authorities for e assertions that strenuous work and play meant a or flow, and that women employed in industry had low fertility-rate. The anxiety connected with mpetitive examinations and games was another ctor in irregularity. He complained of the lack of mparative statistics from which the effect of varying tivity could be inferred.

Growth and Weight.

Dr. ALICE SANDERSON CLOW (Cheltenham) compared e ages of onset in a group of schoolgirls and in a oup of girls at a training college. In the former oup the usual age was 13, in the latter it was 14. ie schoolgirls were the children of well-off parents; e college girls came from humbler but not necessitous mes, and had usually been to elementary schools. ie schoolgirls had a higher average of physique, and is might account for the earlier catamenia. She owed charts of the weight- and growth-rate in lation to the age of onset, to indicate an answer to e question of when delay should be regarded as thological, and inferred the important rule that, long as weight increased and growth continued, no xiety need be felt at the absence of catamenia. ilure of the secondary characters to develop after was very rare. Menstruation should be free from ffering of any kind, and adequate medical attention uld help to bring this about. Dr. Clow remarked at even in these days most educated mothers ught their daughters to consider themselves ill at e period. She had found that girls were delighted be allowed warm baths, games, and gymnastics, hich latter she advised especially on the first two ys. Her instruction had reduced the percentage of sufferers from 46·7 to 10·8 in 13 years. Girls engaged in standing and sedentary occupations were the most liable to dysmenorrhœa, which could be largely abolished by 15 minutes' exercise a day in the open air. Neurotic disturbances were best treated by sound instruction, and by advising healthy activity of body and mind.

Dr. ETHEL VAUGHAN SAWYER agreed that menstruation should impose at the worst a slight lassitude on a healthy woman. There was a close connexion between painful menstruation and toxæmia, especially that resulting from measles or scarlet fever, which caused slight degeneration and loss of tone in the uterine muscle. This was most frequent if the infection occurred at 13 or 14; catamenia was then usually delayed until 15 or 16. "Congenital" ante- and retro-flexion were really, she thought, due to a softening of the uterine muscle resulting from a toxæmia following one of the childish diseases. Concerning hygiene in schools, she recommended a warm bath every day during the period. Cold baths checked the flow, and warm baths stimulated it by easing congestion. Games were too strenuous, but walking, Swedish drill, and dancing were good.

The Psychology of Dysmenorrhœa.

Dr. G. I. STRACHAN (Cardiff) spoke of the subject from the psychological aspect. Gross menstrual abnormalities often occurred without affecting the mind, and menstruation, whatever the text-books said, might be unaffected even in the severest mental disorders. Minor mental disturbances were very rare in the early months of the function. He recommended individual instruction, but questioned whether the mother was necessarily the best person to give it. It was not necessary to insist on any rule, either of continuing to play games or of lying down; the girl should do what she liked. Re-education in healthy living was the treatment for dysmenorrhœa in the absence of obvious organic trouble.

The CHAIRMAN agreed with Dr. Clow that girls in comfortable circumstances and of healthy habits started menstruation considerably earlier than others. Those developing dysmenorrhœa between 20 and 25 usually gave a history of early measles, scarlatina, or septic tonsils, which set up pelvic peritonitis with damage to the ovaries and tubes.

Prof. LOUISE MCILROY (London) said that every normal girl ought to be brought up to ignore menstruation entirely and do what she wanted, but that doctors should not let this principle prevent them from detecting pathological dysmenorrhœa. Menstrual troubles often arose after a girl left school, because she was relatively unoccupied. Unhappy marriage was another cause. Among girls doing manual work the incidence was low, but it was high among sedentary workers. The speaker recommended dancing as the best exercise for the period. Games had nothing to do with fertility, but competitive games and examinations might produce bad after-effects. Intellectual work was an important adverse factor. Contrary to Dr. Strachan's experience, she had found that mental patients suffered from long periods of amenorrhœa, which curettage, an objectionable operation in many ways, did not improve.

Dr. CATHERINE CHISHOLM (Manchester) mentioned two factors producing dysmenorrhœa: nervous strain and overwork with consequent failure of the general health. Examinations caused a failure in health and so made the period painful, and the girl's fear of the next completed a vicious circle. Girls should be taught to report dysmenorrhœa to the doctor, and general practitioners should regard the condition as important. Games were permissible as long as the girl was fit, but they should be part of the curriculum and not a heavy addition to it. This was a fault more common at day-schools.

Dr. MABEL RAMSAY (Plymouth) said that her only dysmenorrhœa patients nowadays were factory workers of about 21, and employers would find it an economic advantage to provide regular exercise. Pathologically-delayed catamenia might be a result of early under-

feeding. Mumps was a virulent source of pelvic trouble. She advocated cold baths and swimming.

Dr. E. FARQUHAR MURRAY (Newcastle) said that amenorrhœa in older girls was often associated with under-development of the uterus, and the patient was then sterile. Another symptom of this was a very scanty discharge and dysmenorrhœa. Very early treatment gave the only chance of improvement. Some authorities recommended ovarian extract and thyroid.

Dr. R. WATSON (Belfast) spoke of the girl with an excessive discharge, who lost blood in serious quantities. She generally had a small uterus which went very soft. The treatment was rest and open air, with Easton's syrup and 1 gr. of ovarian extract three times a day. The speaker deprecated the use of curettage and radium, though Bonney's operation had given good results with one patient who had refused medical treatment. He suggested that many dysmenorrhœa sufferers had a small os.

Dr. LILIAS JEFFRIES (Brighton) condemned the rule forbidding exercise and games, making a girl consider herself sickly for three days out of 28. It was sufficient to require the girls to report the period to their house-mistress, who would leave the hardy ones alone. A most important cause of trouble was constipation due to hurrying into school after breakfast and omitting the duty of clearing the bowels. Ordinary practice games were innocuous, but sea-bathing ought to be given up.

Prof. J. HENDRY (Glasgow) stressed the importance of the general health between periods, advocating very vigorous exercise, like tennis and badminton, for strengthening the abdominal walls and toning the muscles generally, especially just before the period.

Dr. J. H. FERGUSON (the President) remarked that anæmia had diminished in Scottish girls' schools with the improvement of the curriculum.

Dr. W. F. T. HAULTAIN (Edinburgh) put down constipation to drinking too little water, and advised an aperient during the period, a time when bowels were apt to be sluggish. Games and warm baths were useful then, as they stimulated the flow.

Dr. R. T. SUTHERLAND (Melbourne, Australia) wished each girl to be considered as an individual and not subjected to a general rule. He praised the shower-bath, so rare in English schools.

Prof. JOHNSTONE, Dr. PATON, and Dr. CLOW replied.

FRIDAY, JULY 22ND.

At the third meeting, under the presidency of Dr. J. HAIG FERGUSON, the proceedings were opened by a paper from Dr. F. A. E. CREW (Edinburgh) on the

Effect on the Sex Ratio of Conception Early and Late in Relation to the Œstral Cycle of the Rat.

Dr. Crew reviewed the history of scientific opinion on this matter, and pointed out that Thiery in 1863 had maintained that the ovum when first extruded was female, but that at some point in its passage it became male. Thus fertilisation immediately after ovulation would produce female offspring, and later would produce males. Experiments had shown that, if an interval of 89 hours passed between the first and the second fertilisation in the frog, the second half of the eggs were all males, a result which could only be explained by saying that the effects of delayed fertilisation were such as to transform their metabolism, turning them from determined females to determined males. The same results were obtained by desiccation of the toad's egg. Work on the ringdove had suggested the statement that a high metabolic rate led to a physiological state of maleness, and Riddle had extended this to cattle. It was not yet established that the egg does take up water from the genital tract, or that results recorded for amphibia might be applied to mammalia. Nevertheless, there was a suggestion that sex reversal before fertilisation might be possible. A marked difference in the sex ratio of calves from early, late, or middle service in relation to the œstral cycle of the cow had been claimed. It was, however, impossible for the breeder to tell which stage of œstrum a cow was in, but with the new method of vaginal smears the phases of the rat could b accurately determined. Dr. Crew then described son experiments performed by himself on the rat, and th precautions necessary to eliminate secondary factor When the female was fertilised in the first thr hours of œstrus proper, the result of 35 litters w 98 males and 91 females, a sex ratio of 51·84. The were 15 pseudo-pregnancies. When she was fertilise in the last three hours the result of 28 litters w 77 males, 82 females, ratio 48·43. Pseudo-pregnanci numbered 22. Dr. Crew observed that no o experiment could cope with the numbers necessa for decisive conclusions. It was important for su experiments, therefore, to be multiplied and correlate He concluded that, so far as they went, these resul tended to support the conclusion that time of servi is a factor of no importance in the determination sex in the mammal. He added, however, that rece work pointed to the fact that staleness of the egg w associated with a disturbance of its general metabolis which seemed in some cases to be such as to lead to complete transformation of its characteristics.

In reply to a brief discussion, Dr. Crew added th obstetricians would not long be allowed to ple ignorance of this matter. It was important that o of the accumulation of knowledge should come pow In the human being it had been stated that the e played no part whatever; there were two kinds spermatozoa, which determined sex. Recent wo however, showed that the story was not so simp This mechanism could only operate normally a perfectly normal state of the zygote, and t directing action of the sex-determining mechanis could be transformed by any disturbance in t general physiology of the egg.

Prof. W. FLETCHER SHAW (Manchester) then rea paper reviewing his experience of

Uterine Fibroids after the Menopause.

He said that fibroids might cause symptoms over long range of years, but that most patients began complain between 45 and 50. In considering t advisability of operation the two points to be consider were: (1) that the menopause was often delayed such cases, and (2) the possibility of malignant a degenerative changes in the fibroids afterwards. T more experience he had the more he was impress with these serious later complications. Removal a healthy woman of about 50 entailed very slight ris but the risk was gravely increased in a woman over in whom long degenerative changes had produc chronic ill-health. During the last six and a half ye he had operated on 62 patients, eight of whom w over 60 and three over 70. The symptoms were:

1. General ill-health. Three cases had been too ill operation; many had been enfeebled by a very large fibr and prolapse with increasing pressure symptoms, reduc them to a miserable existence.

2. Malignancy: three sarcomas and three ade carcinomas.

3. Hæmorrhage after the menopause without malignan

4. Acute pain due to advanced degenerative chang associated in two cases with profuse hæmorrhage.

5. Chronic pain.

6. Torsion—a rare complication, but two cases occur in this series. The onset of symptoms might be acute subacute.

7. Torsion of the pedicle of a subperitoneal fibroid: t cases.

8. Pressure symptoms. The normal post-climacte shrinking of fibroids sometimes allowed a previou abdominal tumour to sink into the pelvis, causing retent of urine, pressure on the rectum, or bearing down. Occasi ally the growth increased in size instead, and led frequency of micturition or swelling of the legs.

9. Rapid increase in size, generally due to cy degeneration.

10. Absorption of degenerative products, produc general ill-health, loss of weight and appetite, and anæm

11. Ascites, due to calcareous degeneration wh irritated the peritoneum.

He urged the importance of removing fibroids ea when the patient could stand it, and obviating the r of these later troubles.

Dr. BETHEL SOLOMONS (Dublin) agreed, and s that the people who were advocating X rays w

obably working in the wrong direction. He had en cases so treated in whom malignant degeneration d occurred and who had been quite inoperable nen discovered. To the general practitioner the flex symptoms caused by fibroids were very portant; he had known nervous symptoms, miting, and so on, relieved by removing a fibroid erus. Stovaine spinal anæsthesia was the method choice in some of these cases. Prof. LOUISE CILROY, Dr. GIBBON FITZGIBBON, Dr. J. YOUNG, d the PRESIDENT expressed their agreement. Prof. AW, in reply, remarked that text-books said thing of what happened to fibroids after the enopause. A fibroid uterus had a very much greater ance of becoming malignant than one which had fibroid. Though he would not say that every roid should be removed, yet, taking the risk of alignancy with that of degeneration in a large roid, he would say that every large one ought to be ken out. Spinal anæsthesia was the best method less the anæsthetist were a real artist.

Dr. DANIEL DOUGAL (Manchester) then presented a view of 100 cases of

Ectopic Pregnancy.

these 51 per cent. had aborted, 37 per cent. had ptured, and 12 per cent. remained unaborted and ruptured. The chief predisposing factor was a eceding pelvic infection, which might be visible at eration, except that the results of gonorrhœa were en limited to the tubal mucosa. At least 50 per at., however, would show old-standing adhesions out the non-gravid tube. In addition, puerperal otic infection, abdominal tuberculosis, and appendi- is played an important part; 59 per cent. of tubal gnancies were on the right side. Developmental normalities were contributory causes, and 2 per cent. cases had fibroids. Age was of no importance, nging from 21 to 43. 48 per cent. occurred during e first five years of marriage, and 35 per cent. during e second quinquennial period. 10 per cent. of the tients had been married a year or less. In the wly-married and apparently healthy woman some her cause must be sought; one-third had never had previous pregnancy, while 10 per cent. had had a erine abortion as the result of the only previous tilisation. The series showed some support for the w that ecotpic gestation followed a period of rility. The diagnosis was based on a symptom- mplex including amenorrhœa—not usually longer an two months—irregular uterine hæmorrhage, and dominal pain. Very acute cases, where the peri- neal cavity was flooded with blood, might complain shoulder-pain. The bleeding continued after the cidua had come away; it might be due to chorionic li left in the tube. The importance of the symptoms pended on their combination; all three were esent in 64 per cent., and bleeding and pain in per cent. The order was amenorrhœa, pain, eding. There were three clinical types: (1) where e ovum stayed in the tube, causing little or no emorrhage into the abdomen, 13 per cent.;) profuse intraperitoneal hæmorrhage, 27·6 per cent.; d (3) gradual or repeated hæmorrhages, 62 cases. ie patient might be prostrated by the profuse emorrhage or might react to it, so that when erated on she resembled a case of the third type. vestigation of the symptoms might reveal, in dition to the three cardinal ones, pain on micturi- n, dyspareunia, pain on defæcation, and retention urine. The patient looked ill and had generally me degree of anæmia. The temperature might be er 100° F. The abdomen was tender and showed her a sensation of resistance over the pelvic brim a tumour capable of displacing structures, but there uld be no rigidity. The treatment was surgical, d the sooner the better; expectant treatment was ngerous, except to improve the general condition severe cases of shock. The particular operation pended on the type of case and condition of the tient. The gravid tube should be removed. Some thorities removed both, as second cases in the maining tube were not uncommon, but this was going too far, as many had normal labours subsequently. The prognosis was good; there had been no deaths in his series; 43 cases had no further pregnancy; 46 per cent. had subsequent uterine pregnancy; and 13 per cent. ectopic.

Dr. MABEL RAMSAY (Plymouth) related her experience of ectopic cases, and Dr. H. LEITH MURRAY (Liverpool) maintained that repeated peritoneal tearing was most unusual, as an investigation of his cases had never shown round-celled infiltration of the edges of tears. He strongly advised appendicectomy, as he regarded the appendix as a fruitful source of ectopic gestation.—Dr. BETHEL SOLOMONS spoke of the difficulty of diagnosis and the inconclusiveness of so-called tests for pregnancy. Diagnosis had to be made from general symptoms and sudden onset; even amenorrhœa was absent in many cases. He would rather operate on a kitchen table than move the patient.—Dr. FARQUHAR MURRAY mentioned referred pain in the upper abdomen and the importance of feeling for blood in the pouch of Douglas between a rectal and a vaginal finger. Ruptured ectopics revived remarkably if given a quarter of a grain of morphia and an hour or two's rest before operation.—Dr. W. FORDYCE (Edinburgh) said that rupture into the broad ligament was apt to be overlooked or mistaken for a retroflexed gravid uterus. The symptoms were pain and retention of urine, and it was impossible to define the uterus on examination. Palpation should be extremely gentle.—Prof. R. W. JOHNSTONE (Edinburgh) spoke of the acute pain produced by pressure on the posterior fornix.—The PRESIDENT remarked that ectopic gestation was often mistaken for ordinary abortion.

Dr. BETHEL SOLOMONS then read a paper on

Some Points in the Technique of the Low Segment Cæsarean Operation.

He said that the value of this operation was not recognised in some hospitals, and the technique should be standardised. No matter in what part of the uterus infection lay, the incision in the lower segment was safe. After describing his technique, and quoting illustrative cases, he said that the operation should be done on the patient who had been in labour some time and was not likely to deliver herself, and where the conditions necessary for pubotomy were not present. It allowed of subsequent trial-labour. It was also valuable in placenta prævia. In early labour where the baby was in danger, however, it had no advantage over the classic operation. The longer the labour had lasted and the higher the bacterial content of the uterus, the more advisable was the lower segment operation. The placenta should be delivered through the incision, and the abdomen should be drained for 48 hours in all suspicious cases.

Dr. G. FITZGIBBON spoke in favour of the lower segment section; it was bloodless and easy to suture. He had found that, where the head lay in the iliac fossa, it was not a case of bringing the head into the midline of the uterus, but of bringing the uterus into the midline of the abdomen.

Prof. MCILWRAITH, of Toronto, said that his clinic was turning from the high operation to the low, which had come to stay. He thought, however, that the classic section was admirably suited for placenta prævia.

Prof. J. HENDRY (Glasgow) agreed that the low operation was no good in placenta prævia, although excellent for cases long in labour.

Dr. BETHEL SOLOMONS, replying, justified removal of the placenta by consideration of the risk of catching it in suturing the wound and of adherent placentæ.

Dr. DOUGLAS MILLER (Edinburgh) then read a paper on

Failed Forceps Cases.

He reviewed a series of 500 emergency admissions to Edinburgh Royal Maternity Hospital; 74·6 per cent. were failed forceps cases, due chiefly to disproportion —contracted pelves or large heads. The pelvis was generally rachitic. In one type of case the trouble might not be recognised until the head had reached a low level and the possibility of Cæsarean section had

passed. Occipito-posterior presentations were a second common cause of difficulty—generally unrecognised. Forceps had usually been applied several times, and many patients had severe lacerations. In a third group there were no abnormalities; possibly they were cases of occipito-posterior presentation reduced during the journey to hospital. In the majority of cases, however, the forceps had apparently been applied before the head was moulded, through anxiety to save suffering. Dr. Miller stressed the significance of this series for prophylaxis. Whereas approximately one-third of them were seen by a doctor for the first time after the onset of labour, there had been but three failed forceps cases among 6000 odd patients who had attended the hospital antenatal department. Where moderate forceps traction failed to deliver, further action should be governed by four considerations: (1) What was the nature of the obstruction? (2) Was the birth of a living child per vias naturales possible? (3) If so, was immediate interference desirable or not? (4) If not, did the conditions warrant or forbid a Cæsarean section? There could be no hard-and-fast rule to determine between craniotomy and Cæsarean section when the child was dead. In conclusion, said Dr. Miller, this series showed the importance of antenatal care and routine measurements of the pelvis; the great danger of non-observance of the elementary rules of forceps application, particularly through an incompletely dilated cervix or in the presence of marked disparity; the necessity of recognising the nature and degree of the obstruction, and the remarkable capacity of Nature to overcome considerable disproportion by moulding. The condition rather than the number of hours passed should constitute the indication.

SECTION OF THERAPEUTICS AND PHARMACOLOGY.

WEDNESDAY, JULY 20TH.

THIS Section met under the Presidency of Prof. J. A. GUNN (Oxford). At the first session a discussion on

CLINICAL METHODS OF ADMINISTRATION AND THERAPEUTIC USES OF OXYGEN

was opened by Dr. H. WHITRIDGE DAVIES (Edinburgh) in the absence of Dr. E. P. POULTON (London).

Dr. Davies said that the need for administration of oxygen arose whenever the tissues were labouring under oxygen-lack. These conditions could be divided into three types: (1) anoxic, due either to lack of oxygen in the atmosphere or to impairment of gaseous exchanges in the lungs in pulmonary lesions; (2) anæmic, due to hæmoglobin deficiency; and (3) stagnant, due to impaired circulation. The untoward effect of all three conditions could be overcome more or less completely by the administration of oxygen, but the amount of oxygen required varied. In the anæmic and stagnant types it was necessary to increase the amount of oxygen in simple solution in the blood plasma. This could only be done by increasing greatly the partial pressure of oxygen in the alveolar air. If the subject inspired pure oxygen the amount of oxygen in combination with hæmoglobin would remain unaltered, but the amount in simple solution in the plasma would be increased to 2·2 volumes per cent., an amount sufficient to overcome the deficiency of oxygen in the tissues in some cases of anæmic or stagnant oxygen-lack. In the anoxic type such high alveolar pressure was seldom, if ever, necessary. Clinically, cases of pneumonia, pulmonary œdema, acute bronchitis, and other acute and chronic inflammatory diseases of the lungs fell into this category. Owing to inflammatory or œdematous thickening of the pulmonary epithelium oxygen passed into the blood less readily than normally, and increased partial pressure of oxygen in alveolar air was therefore required.

Dr. Davies went on to discuss the methods of administration in general use. The oxygen chamber was excellent when prolonged oxygen treatment was necessary, but its high initial cost, the necessity fo skilled supervision, and the danger of fire restricte its use to a few large institutions. Similar result could, however, be obtained by closed-circuit method of oxygen administration; he described various form of apparatus and showed how the percentage o oxygen given and the percentage in the alveolar ai could be calculated. Methods in which oxygen flo was automatically cut off during expiration were t be preferred for they doubled the efficiency obtaine with any given flow of gas. The ordinary tube an funnel method of giving oxygen, which was eve now seen in some hospital wards, was practicall useless.

The earliest method by which oxygen could b administered in a quantitative manner was that o Haldane, which merely had the disadvantage that was almost impossible to obtain an alveolar pe centage of more than 60. Such a high concentratio was, however, seldom necessary. A further di advantage was that the apparatus afforded no mean for determining the total respiratory volume pe minute, and unless this was independently obtaine it was impossible to calculate the alveolar air pe centage. In order to overcome this deficiency D A. R. Gilchrist and he devised a modified form o apparatus.[1] Precise knowledge of the alveolar a percentage was more than a mere academic nicet Not only was there the satisfaction of producing definite effect but also an estimate of the percentag of alveolar oxygen necessary to abolish the sympton of oxygen-lack afforded a quantitative indication the severity and extent of the pulmonary damag When not more than 40 per cent. of alveolar oxyge was needed—i.e., when the rate of oxygen flow wa not more than one-third of the respiratory volum per minute—the mask first used could be dispense with and a forked nasal tube could be used instea which was much more comfortable for the patien

The first criterion of successful administration wa the abolition of cyanosis; but since oxygen-lac occurred before the advent of cyanosis rather mo oxygen should be given than was necessary to aboli the cyanosis. The second criterion was the relief dyspnœa. Respiratory embarrassment was alway aggravated by oxygen-lack, but since it might be du to other causes it could not always be abolished b oxygen. The third was a fall in the pulse-rat This was probably the most reliable criterion an occurred even in normal people when increase percentages of oxygen were breathed. It was eve more marked in pathological cases. Oxygen therap in pneumonia resulted in diminution of restlessnes promotion of sleep, and tendency to lessened deliriu Delirium should be prevented by early administratio of oxygen for it could not always be cured by oxyge later. Very good results had been reported fro oxygen administration in war gas poisoning an chronic bronchitis and emphysema.

A paper by Dr. W. T. RITCHIE (Edinburgh) wa read in his absence by Dr. C. G. LAMBIE. All wh were engaged in the practice of clinical medicine wer he said, confronted daily with the problem anoxæmia in certain patients. Dyspnœa and cyanos were the chief clinical manifestations of this co dition. Dyspnœa preceded cyanosis and was ofte so urgent as to require immediate relief. Chron anoxæmia might interfere with functional efficienc and ultimately lead to structural changes in organ If dyspnœa and cyanosis were due solely to deficie oxygenation of the blood in the lungs, the deficienc might be met by adding oxygen to the inspired ai Unfortunately, the problem was not so simple nevertheless, this was the basis of oxygen therap The methods of administering oxygen were far fro satisfactory. The volume of oxygen delivered fro the cylinder was only approximately known; w knew even less about the amount inspired by th patient, while that which diffused into his pulmonar capillaries was largely a matter of conjecture. Th

[1] THE LANCET, 1925, i., 916.

mount given must be ample—not less than 2 litres er minute. Oxygen was rapidly absorbed and pidly consumed, so any good effect derived from xygen therapy was extremely evanescent. The xygen should be given as continuously as possible. e recommended a moulded glass mask which he und less irksome than either an oral or a nasal ube. Haldane's apparatus was economical and liable.

Oxygen therapy relieved dyspnœa and cyanosis in me patients. In others it was of no value, probably ecause in these the free entrance of oxygen into the veoli was prevented. In other cases it failed ecause the dyspnœa was due to a pathological crease in metabolism as in hyperthyroidism. xygen was of no service in anæmia because of the ck of hæmoglobin to transport it. The dyspnœa of abetic coma and the terminal phase of renal disease ere not due to lack of oxygen, and could not be lieved by its administration. Cheyne-Stokes breath-g could, however, be relieved by either oxygen or rbon dioxide. Dyspnœa was sometimes a symptom an hysterical attack, and CO_2 relieved this con-tion but not oxygen. In the treatment of circu-tory failure oxygen played a minor part. He used in the later stages but found it of most benefit hen intense dyspnœa had begun suddenly and cently, as in the early phase of auricular flutter, roxysmal auricular fibrillation, and paroxysmal chycardia.

It was in disease of the respiratory system that e need for oxygen therapy was greatest. Here the noxæmia might be due to two factors: (1) the ssening of the volume of air entering the bronchioles, ; in tracheal compression and bronchial asthma; nd (2) interference with the diffusion of oxygen rough the alveolar walls into the pulmonary pillaries, as in acute pneumonia and pulmonary mphysema. In emphysema oxygen afforded more lief than was attainable by any other means. xygen was especially helpful in pneumonia. Every neumonic patient was dyspnœic, but he did not ecessarily need oxygen. The indication for oxygen as cyanosis. The faintest trace was a call for xygen, and the call became urgent when the cyanosis as pronounced. It should be given freely and as ntinuously as possible, and was of more value in ute lobar than in broncho-pneumonia. Anoxæmia as, however, only one factor in pneumonia; in rofoundly toxic cases oxygen was of no avail.

Dr. REGINALD HILTON (London) compared various ethods as measured by their power of raising the rcentage of oxygen in the alveolar air. He regarded e tube and funnel method as absolutely useless if e funnel was held 10 cm. away from the mouth. he efficiency of the nasal catheter was manifestly ss than that of the mask, but for ease and con-enience it was the best. Analyses of arterial blood ere quoted in two cases of pneumonia, which showed at by the nasal catheter even low rates of oxygen ow were able to raise the arterial saturation. The asal catheter was the best to use in general practice, nd should be employed as a routine in pneumonia, which disease it was in many cases the most nportant therapeutic agent we possessed. The xygen should be turned on before the catheter was nnected to the cylinder, and the flow should be as pid as was consistent with the patient's comfort. r. Hilton showed a new mouth mask which, he said, ave better results than could be obtained with the aldane apparatus. The nares were closed with tton-wool. He claimed that it was more comfortable an the face mask.

Dr. C. H. GREEN (Mayo Clinic, Rochester, Minn.) ad been associated with Dr. R. M. Wilder in the mparative study of different methods of oxygen dministration. The oxygen chamber was most fficient for the control of anoxæmia, but it was very xpensive. An excellent substitute was the bed nt, a canvas cloth with an isinglass window which tted over the head and arms of the patient. It ontained an absorber to take out CO_2, there was a motor (the motor being outside the tent to obviate danger of fire) to keep up the circulation of oxygen, and ice to cool the atmosphere. 30–40 per cent. of oxygen was easily maintained in the tent, and with this amount it had been found possible to control cyanosis in broncho-pneumonia, post-operative pneumonia, and pulmonary embolism, which were the conditions of which he had most experience. In pneumonia the effects of oxygen therapy were lowering of the pulse-rate and temperature, the latter dropping 1–4°. In pneumonia there were more factors than simple anoxæmia, and the relief of cyanosis was of no avail if the patient was dying of septicæmia. He thought that the relation of the fall of temperature after oxygen administration to the immunity processes should be worked out.

Prof. C. W. GREEN (Missouri) said that he had studied the question of oxygen-want from the physiological angle. He wished to emphasise what Dr. Ritchie had said, that oxygen therapy cannot be intermittent but must be continuous till the crisis had passed. It was dangerous to give it in a crisis and then to interrupt its administration. The physiological reactions brought about by giving oxygen were very complicated. If oxygen was gradually decreased, without increasing the CO_2, from the normal level to the stage of oxygen-want, there was a rise in blood pressure and an increase in respiration rate and volume up to the crisis, when respiration failed and the blood pressure fell rapidly. If, when this crisis was approaching, oxygen was given, the heart-rate, blood pressure, and respiration were restored to normal; but if the oxygen was then stopped the severest stage of the crisis immediately returned. In pneumonia the patient could not stand the shock brought about by withdrawal of oxygen given therapeutically.

The PRESIDENT (Prof. J. A. GUNN) then read a paper on

Expectorants.

He said that in the course of the last decade there had been notable advances in nearly every department of therapeutics, but in one subject—namely, expectorants—not much progress had been made in the last 10, 50, or even 100 years. Hardly any experimental work had been done on expectorants, and only one or two papers had appeared. He had examined text-books from all countries, and had found they contained mostly repetitions from those of 90 years ago when Christison wrote.

One of the difficulties lay in measuring the secretion from the bronchi and the impossibility in patients of separating it from salivary secretion. A physiologist had recently told the speaker that he had taken large doses of ammonium chloride and had been unable to observe any increase of bronchial secretion in himself. But in a normal person it was not easy to observe increase in secretion. On the other hand, in a person with dry bronchial mucous membrane a very slight secretion became immediately noticeable. In animals the difficulty was not so great. Pieces of absorbent paper were placed on the trachea and the secretion measured by weight. Here, however, the experiment was complicated by the anæsthetic, which in itself produced secretion, and by the fact that different animals reacted in different ways and that the secretion was different in normal and pathological conditions. He wished to make an appeal to clinicians to devise some method of measuring bronchial secretion.

Prof. Gunn then referred to the physiological methods of clearing bronchi. There was a motor and a secretory mechanism. The former was rather complicated. Cough only cleared the trachea and upper bronchi. More important was the movement of the cilia. As a student he had thought it a myth, but now he regarded ciliary movement with profound respect. By means of the ciliograph the movement could be measured. A small piece of ciliated epithelium could be made to move quite a large drum. It would propel solid particles at the rate of at least 1 inch a minute. Therefore it took less than half an hour

to move anything from the depth of the bronchi to the upper air passages. A small portion of the bronchi near the alveoli had no cilia. Possibly this was the reason for the occurrence of bronchiolitis. Another possible mechanism for clearing bronchi was peristaltic movement of bronchial muscle.

The classification of expectorants was most unsatisfactory. Hitherto they had been classified either according to the place where they were supposed to act or according to whether they were sedative and stimulative. For the latter classification there was no justification. Prof. Gunn divided them according to whether their modification was: (1) Reflex, through gastric irritation—tartar emetic, ipecacuanha, senega, squill, potassium iodide, alkalies. (2) Central —apomorphine (emetine). (3) Stimulation of secretory vagal endings—pilocarpine. (4) Stimulation of glands during excretion—potassium iodide, ammonium chloride. He then discussed the action of the various drugs in detail. Ipecacuanha acted better in children than in adults, and was valuable in acute diseases possibly because it had a tendency to lower temperature. Probably it got its reputation on account of this. If the doses were pushed till nausea supervened the expectorant effect was much more powerful. This raised the question whether the stimulus went only to the secretory fibres or to the broncho-motor fibres of the vagus as well. Senega acted in the same way as ipecacuanha; there was no reason for regarding it as a stimulant expectorant and ipecacuanha as a sedative. Squill might come into a different category, but it was first used as an emetic, then as an expectorant, and only later was its cardiac action realised. Its effect was explained by reflex action from the stomach. It also had a central emetic action. Probably it had a more prolonged effect than ipecacuanha, but this had not been accurately measured. Physicians in the seventeenth and eighteenth centuries had a great respect for squill, probably because it was given in large doses and had an effect on the heart. Potassium iodide was a very valuable expectorant, especially in the chronic bronchitis of adults. It acted both reflexly from the stomach and directly on the glands of the mucous membrane. Regarding ammonium chloride there was great divergence of opinion. Some text-books said it increased secretion, some that secretion was diminished, and others that secretion was increased in large doses and diminished in small doses. Clinically it acted as an expectorant. Intravenously it had no effect except in very large doses.

Dr. WHITRIDGE DAVIES said that from personal experience he could say that ammonium chloride acted as a gastric irritant.

Prof. F. J. MCDOWALL (London) said that observations with the bronchoscope showed that there was complete closure of the bronchi during expiration; therefore the bottom part of the bronchi would be squeezed clear with each expiration.

Prof. O. S. GIBBS (Halifax, Nova Scotia) asked whether, if the bronchial tree was emptied by peristalsis, the action of adrenalin would not be to prevent this?

Prof. RALPH STOCKMAN (Glasgow) spoke of the observations of Christison. Many drugs could only be studied in disease, and expectorants belonged to this category. It was difficult to study them satisfactorily in animals. The method of taking up expectoration with blotting paper was too crude to be of value. Many patients with bronchitis had a degenerated mucous membrane and in them drugs would have quite a different action.

THURSDAY, JULY 21ST.

This Section met on the second day to discuss the

THERAPEUTIC USES OF CALCIUM SALTS.

Prof. F. R. FRASER (London) said that an understanding of the indications for administering calcium in disease was made more difficult by the fact that calcium was always present in the body. The serum in health contained about 10 mg. per 100 c.cm., and the amount was remarkably constant. This constancy pointed to some mechanism which maintained a balance between absorption, elimination, and deposition. Only a small proportion of ingested calcium was absorbed, and most of it was passed in the fæces. Elimination of absorbed calcium was by excretion into the digestive tract and to a slight extent in the urine. Certain facts concerning the functions of calcium were well established, others were still vague. Calcium was essential for the clotting of blood and for the proper contraction of heart muscle, and was an essential constituent of bone. Low calcium content of the serum was associated with neuromuscular disturbance and tetany. It also played an important part in the balance of ions in the tissues and fluids of the body. A balance between calcium and magnesium ions and between sodium and potassium ions had been demonstrated in normal life, and the part played by calcium in spasmophilia and tetany must be viewed as exercised through this balance of ions as well as by calcium specifically. Balance also existed between acid and basic ions by which pH was kept constant. Further a balance must exist between the Ca ions and the PO_4 ions and the solubility of the $Ca_3(PO_4)_2$, so that the product of ionic concentration could not rise above a certain level. An increase in the product caused a deposition of solid $Ca_3(PO_4)_2$, and a diminution resulted in the passage of the solid substance from the bones into solution in the body fluids.

The amount of total calcium in the serum was used as an indication of the calcium supply in the living body. It might occur in different states of chemical combination—viz., a non-diffusible fraction combined with protein, a diffusible and easily ionised fraction (about 50–60 per cent. of the total), and an ionised fraction variously estimated as 20–25 per cent. of the total. In considering the significance of departures from the normal values for the calcium content of the serum, it was important to remember that they might affect any of these fractions. Until simple and accurate methods were devised for estimating the available calcium in the blood, its therapeutic uses could not be placed on a satisfactory basis.

Indications for Calcium Therapy.

Nephritis.—The total calcium of the serum was definitely reduced in severe nephritis. In the form with pronounced œdema there was reduction also in the serum proteins. L. Blum and his co-workers had advocated the administration of calcium chloride for the purpose of diminishing the œdema, and in his hands, and in those of many others, it was proved to be an efficient diuretic in many cases. Its action was not due to a specific action of calcium and the restoration of the serum calcium to a higher level. It would appear that it acted by the change that resulted in the balance of ions in the body fluids either (Blum) by increasing the calcium ions, thus decreasing the sodium ions, or by releasing the chlorine ions, thus increasing the acidity, and the excretion of sodium as sodium chloride accompanied by large amounts of water. The latter explanation was supported by the similar beneficial action of ammonium chloride or nitrate. In severe cases of azotæmic nephritis the serum calcium was definitely reduced, and this reduction was accompanied by an increase in the inorganic phosphorus of the serum. No clearly beneficial results had been reported in the form of nephritis by the administration of calcium.

Tetany.—Post-operative tetany was specifically due to the low calcium content of the body fluids, and could be relieved by raising the calcium content. The administration of extracts of the parathyroid glands was able to raise the calcium content of the serum and relieve the tetany. The oral administration of calcium salts in excess could raise the level of calcium in the serum and might relieve tetany, and intravenous administration gave prompt but transient relief. In tetany and spasmophilia accompanying rickets the serum calcium was low. The use of parathyroid extract in rickets was contraindicated except as an emergency, since the increased serum calcium was

tained by the removal of calcium from the bones ich were already deficient in it. The administra- n of calcium salts and cod-liver oil would suffice raise the calcium in the serum to a normal level, t such measures as exposure of the patient or of e patient's food to sunlight or ultra-violet light ght be all that was necessary for the proper treat- nt of the rickets and the relief of the spasmophilia. With regard to other conditions, Prof. Fraser said at low values for serum calcium had been reported various skin diseases, but there was no evidence at deficiency of calcium was of significance in the thology of the disease, and no clear evidence that sing the calcium influenced the course of the ease. Confirmation of the value of calcium erapy in the many and various diseases associated th chronic infections, as found by H. W. Vines d W. R. Grove, was necessary before the scope of lcium therapy could be accepted as embracing e conditions enumerated by them. It was also ficult to accept the evidence available as proof of e value of internal calcium therapy to control morrhage. Blum had shown a powerful diuretic tion of calcium chloride in cardiac œdema. That monium chloride acted in a similar manner ggested that it was the acid property of these ts which was responsible for their action as a uretic, although calcium might have an effect in e same direction by its antagonistic action to dium. The beneficial therapeutic effects of the use calcium chloride in different exudates and trans- ates had been variously reported, but convincing idence was needed that such beneficial actions were e to calcium.

Prof. Fraser then discussed methods of administering lcium, but concluded that indirect methods of fluencing the calcium in the body might be of greater actical importance than the administration of its lts.

Discussion.

Dr. L. G. PARSONS (Birmingham) confined his marks to the effect of calcium in children. It was t necessary to give calcium salts medicinally in der to produce calcification of bone, because the et of a young child contained enough calcium to pply the requirements of the body if absorption as normal. He never prescribed calcium salts cept in tetany. If ionic calcium in the blood was minished tetany would occur, but spasmophilic anifestations might appear under certain circum- ances with an undiminished blood calcium. Pyloric enosis in infants furnished examples of this; in me cases convulsions occurred and recurred and oved fatal, or, shortly after the Ramstedt operation, e child showed a period of apnœa followed by deeper eathing and convulsions. The condition was one alkalosis, and resulted from loss of chloride ions ue to repeated vomiting and high intestinal obstruc- on. In this alkalosis, although the calcium in the rum was normal or higher than normal, the ionic lcium was diminished. On the other hand, in vere azotæmic nephritis, in which the serum lcium might be low, tetany did not occur, ecause there was an acidosis which resulted in more the calcium being ionised. The therapeutic oblem was chiefly how to maintain the ionic calcium such a level that the specific effects of low calcium ould not occur. Dr. Parsons then referred to the uestion of calcium concentration in nephritis and eliac disease. What were the factors concerned in ie absorption of calcium from the alimentary tract, id how could absorption be increased? It had been own that whilst excessive amounts of calcium in ie diet tended to increase its total absorption and tention, they impaired phosphorus retention and ice versa. The retention of one element in the testine by an excessive amount of the other was xplained by the formation of insoluble calcium hosphate. To obtain the maximum absorption of oth they must be properly balanced in the diet; ie calcium should exceed the phosphorus. In ildren one pint of milk daily would meet this require- ment. Another important factor was the presence of fat in the diet. Low calcium retention was found both when there was insufficient fat intake and when large quantities of fat remained unabsorbed in the intestine, as in cœliac disease. The influence of fat on calcium was due to the vitamin D in it. It had been suggested that increased acidity in the upper part of the intestinal tract would increase the absorption of calcium, but this was not entirely borne out by his observations. It appeared that the absorption was not facilitated by the increased acidity per se but by the presence of vitamin D, which itself led indirectly to increased acidity in the intestinal tract.

Mr. C. P. STEWART (Edinburgh) said that Dr. Parsons's clinical observations were borne out by biochemical research. Acidity was a very important factor in the absorption of calcium, at any rate in normal persons. Calcium could only be absorbed after being broken down into Ca ions. If it was given with a protein meal it was ionised by the hydrochloric acid of the stomach and absorbed; if it was given on an empty stomach there was not enough acid and the absorption was poor. If the reaction of the intestine was alkaline, insoluble soaps and calcium carbonate were formed. A distinction had to be made between absorption and retention. Absorption was often normal but the calcium was immediately re-excreted into the large intestine. Retention was associated with vitamin D. Parathyroid hormone was capable of raising serum calcium but it did not increase its absorption. He had obtained the same rise of serum calcium after parathyroid when the whole alimentary canal had been removed from the animal. In further experiments he had isolated and washed out the large intestine and estimated the excretion of calcium after three hours. He then gave parathyroid extract and the same amount of calcium was excreted. It was clear, therefore, that the increased calcium in the serum could only have come from the tissues and ultimately from the bones. Parathyroid was of no therapeutic value in raising absorption but led to depletion of bone calcium. Calcium in the blood was in a partly ionised, partly non-ionised, and partly diffusible form. Our knowledge concerning these forms was vague and it was by no means certain what part ionic calcium played in blood coagulation.

Dr. G. H. PERCIVAL (Edinburgh) said that calcium was intimately associated with cell lipoids. He discussed its action in relation to cell chemistry. Normally there was a very efficient control for keeping calcium constant in the blood. But although symptoms appeared when calcium was diminished, it could be increased by 50 per cent. without any symptoms occurring. During pregnancy and lactation the mother frequently suffered from a deficiency of calcium. A liberal supply of calcium was indicated. Nevertheless, osteomalacia was not affected by giving calcium. In osteitis fibrosa the disease was associated with tumour of the parathyroid. Defence mechanisms were impaired by low blood calcium, but in practice in septic cases the serum calcium was generally normal.

Prof. L. BLUM (Strasbourg) had studied the diuretic action of calcium salts. He showed charts of different cases, the first being one of idiopathic œdema. A salt-free diet with any of the ordinary diuretics had no effect on the condition. If sodium chloride was given the œdema increased. Calcium chloride and calcium lactate produced diuresis and loss of weight, provided that a salt-free diet was maintained. In the presence of sodium chloride, calcium salts had no effect. Calcium chloride was also effective in cases of chronic nephritis with œdema, in the ascites of hepatic cirrhosis, and in inflammatory exudates such as pleural effusion. In the latter there was a fall in temperature during calcium administration. Prof. Blum described a condition which he called dry chloride retention. Essentially, it was an alteration between the balance of sodium, carbon dioxide, and chlorine, and was characterised by a high chloride and low sodium content of the serum. It could be

produced by giving calcium chloride. Its symptoms were dryness of the throat, thirst, and weakness. In this condition it was dangerous to give calcium chloride for then acidosis supervened. To obtain a therapeutic effect it was necessary to give large doses—e.g., 5 to 10 g. Unfortunately, the drug was unpleasant to take and it induced vomiting, diarrhœa, or constipation, but no other calcium salt could replace it.

Dr. G. C. LINDER (London) gave the results of some studies on cases of tetany. Tetany was a syndrome produced by various means. It was associated with deficient parathyroid secretion, and low calcium and high bicarbonate content of the serum. Loeb had been the first to discover that neuromuscular irritability depended on sodium and calcium ions. In tetany the sodium in the serum remained fairly constant, but the calcium altered. After discussing fully the theory of tetany he gave the results of treatment in a number of cases. The charts of a case of postoperative tetany were shown and indicated the difficulties met with in a case which at first sight might have appeared simple.

Dr. N. C. F. BURGESS (London) had studied calcium metabolism in various types of skin disease. He described a method for estimating calcium in the blood, and distinguished between that obtained by analysis of the ash and that estimated by direct precipitation in the serum. Pathological cases fell into two categories: (1) those in which the total calcium was normal but the precipitated calcium was diminished, (2) those in which both were diminished. He criticised the results of Percival and Stewart because they worked only with precipitated calcium. His results confirmed the work of Vines. He analysed 67 cases of skin disease, in many of which, especially those of urticaria and dermographia, the serum calcium was low and calcium therapy was effective.

Dr. C. G. LAMBIE (Edinburgh) gave an account of calcium metabolism in osteitis fibrosa, a disease characterised by rarefaction of the bones and the occurrence in them of giant-celled tumours, and by hypertrophy of the parathyroids. The blood showed hypercalcæmia of 17 per cent., slightly low inorganic phosphorus, normal urea, and chlorides, normal coagulation time, and CO_2 combining power increased by 5 per cent. There was enormous output of calcium in the fæces and a negative calcium balance.

Dr. MYERS spoke of calcium in relation to nephritis.

The PRESIDENT (Prof. J. A. GUNN) asked whether calcium altered the diffusibility of membranes. He cited some experiments of his own in support of the hypothesis that it did.

FRIDAY, JULY 22ND.

The subject of discussion on the third day was

THE ACTION AND USES OF OVARIAN EXTRACTS.

Prof. W. E. DIXON (Cambridge) said that the subject was still sub judice. The ovary, all were agreed, was an organ of internal secretion. If it was removed the animal or human being at once lost its characteristic sex cycle which could be brought back by transplanting a suitable piece of ovary. Twenty-four instances of pregnancy occurring in women after complete removal and retransplantation of ovaries had been reported. The ovarian gland was specific for sex. If it was grafted into a spayed female the œstrus returned and so did the sexual characteristics. In the male, female characteristics appeared, the animals became feminised, and some of the features of œstrus were produced. The growth and function of the ovary was dependent on more than the ovary itself. Something in the body caused the ovary to become active. If a mature ovary was grafted into a young animal it did not function, but if an ovary from a young animal before puberty was grafted into an adult animal it developed and functioned. It could therefore be accepted that the ovary was an organ of internal secretion; the question was how far could that secretion be replaced by artificial extracts?

The ovary differed from other glands because it functioned in a cyclic manner. The corpora lutea underwent stages of development, full functional activity, and regression. Owing to the difference between a degenerate corpus luteum and a growing one extracts of ovary prepared during œstrus and during quiescent periods might give different results. Ovarian therapy had been disappointing for various reasons: (1) the extract might have been taken haphazard from any kind of ovary; (2) physicians gave the extracts in so many different ways; (3) extracts of ovary supposedly containing three different substances were on the market. The first of these substances was œstrin, a definite substance prepared from the ovaries of animals by treating them with lipoid solvents. It had not yet been obtained in pure form, but injected into animals it produced effects leading to œstrus or menstruation (the two were not homologous). It was sold under various names and was prepared principally from the placenta. It was said to be present also in the corpus luteum and was found in the blood of pregnant women after the fifth month and in pregnant animals. Injected into animals it produced development of the sex organs, growth of the uterus, and artificial œstrus. If injected before puberty it was said to lead to œstrus. In order to study the substance and to compare different samples it was necessary to have some method for quantitatively determining its activity. There were three ways of doing this. The vaginal smear method for which rats and mice were used consisted in removing the ovaries, making sure by the examination of vaginal smears that periods of œstrus were no longer occurring, and then injecting the drug and finding the minimal amount which would produce œstrus. The objection to the method was that it was possible to get both positive and negative results with the same sample, and also that the effect was not quite specific for the same result could be got with orchitic extract. The second method was to inject the extract into very young rabbits and watch the development of the uterus. Marked hypertrophy occurred with œstrin. Thirdly, isolated organs showed increase in conductivity of the muscle wave, but many other substances also had this effect. Clinically use of œstrin was indicated when effects leading to menstrual function were required, but so far its use in human beings had not been satisfactory.

The second ovarian substance was obtained from the corpus luteum. In a pregnant animal if the corpus lutea were removed the animal aborted. The experiment was done on rabbits, dogs, and goats in Cambridge, and all but one goat aborted. Afterwards it was shown that one corpus luteum had not been removed from the goat. The injected extract inhibited the period of œstrus; therefore it was the lutein substance which was really responsible for the sexual cycle. So long as the corpus luteum governed the ovary there was no œstrus; when the corpus luteum degenerated the œstrus was released. Persistence of the corpus luteum led to sterility. In support of which view Prof. Dixon quoted Raymond Pearl's experiments on laying fowls; corpus luteum extract was injected into laying fowls and they ceased producing eggs till the injections were stopped.

For the third extract Prof. Dixon was himself responsible. If a watery extract of the ovary was made at certain periods—i.e., in pregnancy, especially just before parturition, and, to a slight extent, during menstruation—its injection was followed by secretion from the posterior lobe of the pituitary body into the cerebro-spinal fluid. Changes in the pituitary gland were closely associated with pregnancy. In a man the organ weighed 0·6 g.; in a nullipara it also weighed 0·6 g.; in a primipara the weight increased to 0·8 g. and the increase was permanent; in a multipara the average weight was 1·1 g. The posterior lobe of the pituitary had a specific effect on the uterus—it provided, in fact, the normal stimulus to contraction of the uterus. This was the most important function of the pituitary, and its secretion could be tested for in the cerebro-spinal fluid. With Prof. F. H. Marshall he had detected it in many experiments in which extracts made from the ovary at these special times

were injected into animals. In human subjects it was found that cerebro-spinal fluid taken from women during Cæsarean section produced labour when injected into other women in whom labour had not yet begun. A pregnant rat or mouse when injected with œstrin aborted up to the fifth day. Large doses were needed to effect this on the fifth day, and after that time no abortion was produced. Pituitrin in the early stages did not produce abortion, but it acted more and more easily as pregnancy went on. Finally, a very small dose was sufficient to start labour. In this way it could be explained why the uterus carried its burden for so many months and then emptied itself.

Miss KATHARINE H. COWARD, D.Sc., spoke on the

Standardisation of Ovarian Extracts.

The method proposed for the assaying of the œstrin-content of ovarian extracts was based, she said, on the œstrus-producing property of that substance. The œstral cycle, recurring generally at five-day intervals in the normal rat or mouse, was inhibited completely when the ovaries were removed. It could be induced in such a rat by the injection of an ovarian extract from apparently any other species of animal. The response to injections varied very widely in different rats, some of them failing to respond to a dose of extract which was as much as ten times the amount effective in other animals.

To obtain a "curve of response," 90 rats were ovariectomised, and each one was given subcutaneous injections of 2·5, 7·5, 12·5, and 17·5 mg. of a particular extract at intervals of 14 days. The result was plotted as percentage response against dose, and gave a flat S-shaped curve. Then a dose of 10 mg. of the same extract was given to each of the 90 animals. The percentage response fell on the theoretically correct place in the curve, which indicated that the extract had not deteriorated in value, or had the rats become less sensitive. Half the rats were then given 10 mg. of the same extract again subcutaneously, the other half 10 mg. intraperitoneally. There was practically no difference in the percentage response of the two groups. Neither was an injection in three parts more effective than a single injection of the whole amount (10 mg.). About the same time 70 mice were ovariectomised and given exactly similar doses. The curve of response fell exactly on that for the rats.

This result, said Dr. Coward, was very remarkable, and indicated that the dose required was independent of the body-weight of the animal, which is also evident from the results on individual rats. It was also surprising that rats which responded to a certain dose did not always respond to a higher dose. It was proposed to adopt as the unit of œstrin that amount of a preparation which would bring about a response in 50 per cent. of the animals tested, 20 animals being used in a test. By referring the response attending any given injection to the standard curve the bulk that would contain enough œstrin (1 unit) to bring about a 50 per cent. response would be found, and thus the sample could be assayed.

Experimental and Clinical Results.

Mr. A. S. PARKES, D.Sc., had sterilised mice by means of X rays and had destroyed the follicles and the corpora lutea; nevertheless periods continued. Therefore the cycle was not dependent on Graafian follicles or on corpora lutea. Œstrin had originally been isolated from the liquor folliculi, but it was also present in the placenta. In pregnancy the corpus luteum had a definite action, inhibiting ovulation and menstruation. In testing extracts of corpora lutea for inhibition of œstrin it was found that some produced œstrus. Further research had shown that the œstrus-producing substance was only found in the fluid in hollow specimens of cow's corpora lutea which was derived from the liquor folliculi. With regard to Pearl's hens, they had stopped laying because they died, killed by the toxic extract. Experiments for the removal of corpora lutea during pregnancy were vitiated by the shock attending the operation, to which the subsequent abortion might well be due. To avoid this he used mice in which one ovary was sterilised by X rays and the other was sound. At various stages of pregnancy he removed one or other ovary. Animals in whom he had removed the non-sterilised ovary all aborted. The sterilised ovary contained no corpora lutea. Degeneration of the corpus luteum brought on parturition. The corpus luteum was also responsible for the development of the mammary gland. Up to two years ago, however, no extract of corpus luteum had been made which produced any action whatever. The œstrus-producing hormone had been available for some years. At least two kinds of cells went to the making of the corpus luteum, so that it probably produced more than one type of secretion. The problem was growing very complicated. They now to all appearance had five types of ovarian secretion: a sex-producing hormone, an œstrus-producing hormone, two produced by the corpus luteum (only one of which was definitely known), and a substance producing parturition.

Dr. W. R. ADDIS (Manchester) spoke of the clinical results of ovarian therapy. He had used ovarian hormone without corpus luteum to induce labour, and had had some gratifying results, but also many disappointing ones. At St. Mary's Hospital, Manchester, he at first had only two successes out of 11 cases, but with improved methods of administration he succeeded in four out of five cases. All of these patients were elderly primiparæ, their average age being 35, and labour was long. He gave on an average 4·5 injections of 1 c.cm. of the extract. Contractions began ten minutes after injection and closely resembled those of the first stage of normal labour—i.e., there was contraction and retraction of the upper segment and relaxation of the lower uterine segment. The first point of interest was that for a long time there was no consciousness of the contractions on the part of the patient. Later she was conscious of contractions, but there was no pain. Pain only began when the presenting part met with obstruction at the cervix, and of course during dilatation of the perineum. This was exactly what happened during labour in animals and in savage races. There was a lack of feeling of tension over the abdomen. On vaginal examination there was absence of marked tension on the fornices during contractions. At first the cervix did not dilate; as soon as it did so the patient became conscious of contractions. Tension must, of course, be present, but was not so great as that usually described. The speaker drew a comparison between normal labour and intestinal movements. Labours induced by ovarian extract approximated to those seen among uncivilised races. He was convinced that the action of ovarian hormone on the uterus was specific and that it worked directly through the autonomic system. Pituitary extract acted directly on the muscle-fibres, and it was difficult to conceive of a substance acting on muscle which would produce the complicated balanced action of labour. His experiments on decerebrate cats in which the pituitary had been removed showed that injection of ovarian extracts produced regular contraction of the uterus.

Dr. THEODORE HAULTAIN (Edinburgh) said that whenever both ovaries were removed he put the patient on ovarian extract made from the whole ovary. He had sent out a questionaire to patients on whom he had operated during the last five years and had received 31 replies. A table compiled from these showed that there had been far fewer complaints of obesity, depression, flushes, headaches, and nervous symptoms among patients who had received ovarian extract. In his experience the results of removal of the ovaries for chronic salpingitis were far worse if the uterus was left than if it was removed with the ovaries.

Dr. KENNEDY remarked that he had collected literature on ovarian medication. It was hard to judge of its efficacy because of the multiplicity of methods adopted and the different preparations of ovaries in all stages of development that were given. He did not agree with Dr. Parkes that there had been no active preparation of corpus luteum until two years ago. Dr. C. J. Hertz had given an extract of it intravenously in pernicious vomiting with very good

results. He himself had produced an extract which he used for experiments on rabbits. The water-soluble extract inhibited ovulation. If ovulation was inhibited for from three to five months atresia of the follicles followed. The œstrus which sometimes occurred after injection of corpus luteum was due to the liquor folliculi often present in cysts in the corpora lutea of cows from which the extract was generally made. If the corpora lutea, when taken out of the body, were chopped up and washed in ice-cold water the œstrin was got rid of. He wished to ask Prof. Dixon about the relation of pancreatic secretion to pituitary and ovarian secretion. When the corpus luteum was removed there was a diminution in the number of islets of Langerhans, and with development of the corpus luteum they increased. The blood-sugar curve ran parallel to the ovulation cycle in birds and probably also in mammals. He asked Dr. Parkes for further details on the cells of the theca and the membrana granulosa in the composition of the corpus luteum, since the type of cell varied in different species of animals.

Dr. CAMPBELL could not help wondering, after listening to the discussion, why the male had dared to develop a posterior lobe to his pituitary. He and Dr. Scott had investigated the question of the action of œstrin with regard to blood-sugar. The injection of œstrin had no effect on blood-sugar whether injected alone or with or before insulin. The watery extract of ovary had also no inhibiting effect on insulin.

Prof. C. W. GREEN said that Dr. E. Allen, working with monkeys in Missouri, had removed one or both ovaries. With the follicular extract he had been able to re-establish menstrual flow in animals deprived of both ovaries. When the follicular fluid was injected there was a considerable growth of the mammary gland, which showed that the corpus luteum had nothing to do with this phenomenon.

Prof. DIXON, in reply, said that Dr. Parkes had made it clear by his experiments that in the mouse the corpus luteum was essential for the continuation of pregnancy. He agreed with Dr. Addis's facts but not with his conclusions. Dr. Addis had in reality described the typical action of pituitary. Its action was to increase the irritability of the uterus, so that the slightest stimulus produced an effect. It was only when doses far in excess of physiological amounts were used that it had a direct action on muscle. Ovarian extract had no action on the autonomic nervous system. In reply to Dr. Campbell he said that all the endocrines worked together, but there was antagonism between pituitary and insulin. The easiest way to get pituitary secretion was to reduce the blood-sugar. He paid tribute to the work of Allen and Doisy, who were the pioneers in the standardisation of ovarian activity.

Prof. D. MURRAY LYON then read a paper on the Action of Digitalis, in which he gave a statistical study of the effects of digitalis in patients with fibrillation, cardiac cases with no fibrillation, and normals, and showed some of the variations of its action in the three classes.

EXHIBITION OF DRUGS, SURGICAL INSTRUMENTS, FOODS, AND APPLIANCES.

IN the last issue of THE LANCET we briefly noticed some of the more important exhibits at the trade exhibition held at Waverley Market Hall from July 18th–22nd. Hospital and Laboratory Equipment, Books, Spas, and Miscellaneous Exhibits are now dealt with.

HOSPITAL AND LABORATORY EQUIPMENT.

[47] Hoskins and Sewell, Ltd. (Bordesley, Birmingham), had a new "Sunderland" bed with the patent castor pad action, worked through the ordinary four legs; a new silent sliding-side-rail cot, a long, narrow cot as used at Alton, a new cot-bassinett with let-down side rails, and a very light, stron "Dudley" road-wheeling ward screen made through out of welded tube without nuts or screws. Thei all-in-one ward locker combines drawer, cupboard seat, and extending table, and they are the designer of the "Alton" sunshade.—[118] Lawson Tait Bed steads (Whitfields Bedsteads, Ltd., 109–125, Watery lane, Bordesley, Birmingham) showed the improve cardiac bedstead as made for University College London, a child's cot with improved wheeling arrange ment and drawer, the Lawson Tait head and kne rest bedstead for the Fowler position, the Pearso fracture bedstead, and other hospital apparatus.— [117] Baird and Tatlock (London), Ltd. (14–15, Cross street, Hatton-garden, E.C. 1), showed all kinds o bacteriological and medical apparatus, made in thei own factory, especially a new wide-range contro incubator, from room temperature to 80° C., and th new Sinclair Mills apparatus for automatically stainin slides.—[119] Messrs. Chas. Hearson and Co., Ltd (Hope Works, 68, Willow-walk, Bermondsey, S.E. 1) showed many pieces of apparatus, including a nev high power binocular microscope by Reichert, capillary microscope, an epidiascope, a new dark field condenser with built-in source of light, rotary encased rocking microtome with automati transporter and section conveyor adjustment fro 1 to 25 μ, and an optical bench, for transmitted an opaque objects, with cinema attachment. Hig speed centrifuges with capacities from 10–500 c.cm buckets and speeds from 3000 to 10,000 r.p.m. wer demonstrated.—[90] Ogilvy and Co. (20, Mortime street, W. 1), agents for E. Leitz, Wetzlar; Coupri Lyons; and Frank and Heidecke, Brunswick, showe a complete range of research and routine instrument including new Leitz microscopes, new fine adjust ment slides with ball bearings, micro-camera attach ments, interchanging mono- and bin-ocular bodie hæmocytometers, &c.

X Ray and Light and Heat Apparatus.

[74] Philip Creswick (132, Wellington-stree Glasgow) showed various accessories for X ray an ultra-violet light work; a 30 m.a. set by the Solu Electrical Co., comprising high tension and Coolidg filament transformers on an all-metal control table on a trolley, forming a compact movable set. Othe exhibits were a new non-corrodable and solderles filmhanger and a seriascope for duodenal exposures —[89, 92] The British Hanovia Quartz Lamp Co., Ltd (Slough, Bucks), showed lamps for ultra-violet therapy Special models were the Jesionek Quartz lamp fo irradiation of several patients at once (suspensio types with big double burners, as used by Gauvai and the Finsen Institute, were shown) and the Cemac Photostat, a new form of mounting with beautifu control, for pharyngeal work.—[41] The Dowsin Radiant Heat Co., Ltd. (91/93, Baker-street, W. 1 demonstrated all kinds of electrical appliances drawing special attention to the "Ultradescent," an appliance containing four radiant heat and on "Ultra-vi" lamp, for combining the applications Ceiling and floor models of the latter were show and recommended for home use under medica prescription.—[35] The Medical Supply Associatio (167–185, Gray's Inn-road, W.C. 1), in addition to universal operating table, pneumothorax apparatus Hawley's new extension apparatus, and a variety o anæsthetic apparatus, were showing a good deal o X ray material, including the "N.P.L." installatio for small hospitals and general practitioners; th "Metalix" tube, wherein the rays are generate within a metal cylinder so that it embodies its ow protection; and the "Trinity" ultra-violet ligh apparatus, designed to provide radiations of the carbo arc, tungsten arc, and mercury-vapour burner.—[46 G. E. L. Rowarth (130, George-street, Edinburgh had as their principal exhibit a 30 milliampere trans former unit and a 20-inch induction coil unit, bot manufactured by X Rays Ltd. (London), for whic this firm are the sole Scottish agents. The former i

signed to utilise the 30 m.a. self-rectifying Coolidge be at an equivalent spark-gap of five inches for ltine radiography. The latter is a powerful set ich can be used with either gas or hot cathode oes.—[43] Victor X Ray Corporation, Ltd. (Morley use, 314–322, Regent-street, W. 1), showed X ray d ultra-violet apparatus and accessories, notably new design of portable electro-cardiograph and all oes of Coolidge X ray tubes, including the new 0 m.a. radiographic type and the 50 m.a. water-oled deep therapy tube.—[107] Radiation, Ltd., owed modern hygienic gas grates made by Arden ll and Co., The Davis Gas Stove Co. Ltd., Fletcher ussell and Co. Ltd., The Richmond Gas Stove and ter Co. Ltd., Wilson and Mathiesons, Ltd., and hn Wright and Co. All these incorporated the Radiation" patent "Injector-ventilator." The New World" gas cooker has also the "Regulo" tomatic heat controller, which enables food to be oked without attention. The stand was illustrated diagrams showing the results of research which is ing conducted on the emission of energy at various ve-lengths from gas fires. A demonstration burner s on view. At another stand were shown the tcher Russell range of dental appliances.—3] The Radiocoil Electro Magnetic Blanket and Pad, d. (4, Manchester-street, W. 1), is a means of heating whole body by electro-magnetism. The wires lined by quilted satinie and covered with camel-ir fleece. A complete demonstration outfit was ently supplied to University College Hospital.—3] The Thermal Syndicate, Ltd. (Vitreosil Works, allsend-on-Tyne; 3 and 4, Old Pye-street, S.W. 1), owed a selection of transparent vitreosil; chemical d laboratory apparatus; mercury-vapour lamps, &c.

Miscellaneous.

[4] The Inhaling Drug and Apparatus Co., Ltd.), Grosvenor-place, S.W. 1), showed, as in previous hibitions, the Spiess-Drager drug nebulising and naling apparatus for producing dry vapour in gulated flow and density.—[32], [67] Aids for the af were demonstrated by General Acoustics, Ltd. 7, Wigmore-street, W. 1), and Mr. R. H. Dent 09, Oxford-street, W. 1). The former especially owed their very small "Shellacon" pattern with earpiece the size of a farthing, the entire apparatus ighing a few ounces only. Also on view were the ltiple Church Acousticon, as used at Wembley, d a testing set with a series of microphones and rpieces to guide practitioners in prescribing. Mr. nt had developed amidst his wide range of appliances "button type," the smallest ever made, and a ecially disguised microphone in the form of a wrist tch. The "Ardente" stethoscope was again shown. [57] Short and Mason, Ltd. (Tycos), (Atlantic House, –50, Holborn Viaduct, E.C. 1), showed their usual riety of Tycos sphygmomanometers, thermographs, d barographs, and had a most interesting new ording sphygmomanometer giving on a chart a ord of the systolic and diastolic pressures. It is worked from the pressure system, and is provided th a double cuff to cut out oscillations. With it es a Spirometer to measure the exercise taken tween two pressure readings.—[86] Kodak, Ltd. .C. 2) gave special prominence to a system of ll-bladder visualisation, opening up a new field r X ray work, and to dental negatives illustrating e "Bite-Wing" system for early detection of inter-oximal cavities.—[2] Fassett and Johnson, Ltd. 6, Clerkenwell-road, E.C. 1), showed a range of ticles including dental floss, "Poppy" corn caps; celluloid vaccination shield with airholes, lead and mphor boil-plasters, Angier's emulsion and abury's Gold Cross absorbent cotton. Of particular terest among the varieties of Mead's and zinc tide plasters was the new "Multiwidth" spool, ntaining ¼ in., ½ in., ¾ in., and 1½ in. tapes on one el.—[48] Johnson and Johnson (Great Britain), Ltd., Slough, displayed ligatures and sutures, toilet owder and plasters. Their Zobec sponges are iform in size, weight, and texture, and their K.Y. lubricating-jelly is a greaseless water-soluble product which will not stain clothing or fog mirrors. "Band Aid" is a neat little antiseptic dressing fastened to a piece of plaster, ready to apply to any minor injury. —[20, 29] The well-known Thermogene Wool and Antiphlogistine were on show.—[54] G. F. Merson, Ltd. (St. John's Hill Works, Edinburgh), claim to be the pioneer manufacturers of sterile catgut and carry the process right from the intestines of freshly killed Scottish sheep to the finished ligature. They drew special attention to their "Mersutures"—eyeless needle sutures for intestinal work, and to "iod-aseptic" preparing spirit for cleansing "sterile-interior" dry catgut.

BOOKS.

[28] William Bryce (Edinburgh) displayed important and recent publications in every department of medical science, and supply the works of all houses in this country, America, and the colonies at the publishers' rates.—[10] Messrs. J. and A. Churchill (7, Great Marlborough-street, W. 1) had a wide range of medical works including the new edition of "Psychological Medicine" (Craig and Beaton); L. A. Parry's "Some Famous Medical Trials"; Romanis and Mitchiner's "The Science and Practice of Surgery," in two volumes; Rowlands and Turner's "Operations of Surgery" 2 volumes; Sequeira's "Diseases of the Skin"; and "Handbook of Ophthalmology," by Neame and Williamson Noble. Of the popular "Recent Advances" series the latest are "Hæmatology" and "Ophthalmology." "The Medical Directory," published by this firm, is in its eighty-fourth year.—[105] The Food Education Society (24, Tufton-street, Westminster, S.W. 1) showed publications on dietetics and hygiene, including "The Diet of Brain Workers" (enlarged) and the old favourites "Facts for Patriots" and "The Pudding Lady's Recipe Book." Graters (for suet, cheese, and winter salads of root vegetables) and "Bickiepegs" for teething babies were also on view.—[106] H. K. Lewis and Co., Ltd. (136, 140, Gower-street, W. 1), included in their extensive display of books and medical stationery "A Manual of General Medical Practice," by W. Stanley Sykes; "Ultra-Violet Rays in General Practice," by W. A. Troup; "X Ray Apparatus," by P. K. Bowes; "Pyelography," by Alex. E. Roche; "Clinical Neurology," by E. A. Strecker and M. K. Meyers; and J. G. de Lint's "Atlas of the History of Medicine, Part I., Anatomy."—[25] The House of E. and S. Livingstone (16, 17, Teviot-place, Edinburgh) drew attention to its most recent publications: Lee's "Diagnosis and Treatment of Venereal Disease"; Muir's "Bacteriological Atlas"; Chapman's "The Heart and its Diseases"; and new editions of Russell's "Ultra-Violet Radiation" and McKendrick and Whittaker's "X Ray Atlas."—[77] Oliver and Boyd (Edinburgh and London) and James Thin (Edinburgh) showed medical and scientific publications, notably Guy's "Pulmonary Tuberculosis"; Dowden's "Fractures"; Eason's "Exophthalmic Goitre"; Thomson's "Sick Children"; and the *Edinburgh Medical Journal*.—[71] The Oxford University Press (Amen House, Warwick-square, E.C. 4) have recently published a fourth edition of Tod's "Diseases of the Ear"; a second edition of Price's "Textbook of the Practice of Medicine"; Wright's "Applied Physiology"; Harris's "Neuritis and Neuralgia"; Wyard's "Diseases of the Stomach"; Sinclair's "The Thomas Splint"; Henderson and Gillespie's "Textbook of Psychiatry"; Thomson and Gordon's "Chronic Rheumatic Diseases"; and D. A. Crow's "Ear, Nose and Throat in General Practice"—just out.—[6] Among the books shown by W. B. Saunders Company, Ltd. (9, Henrietta-street, Covent-garden, W.C. 2), were "Abdominal Operations," by Sir Berkeley Moynihan; "Mayo Clinic—Collected Papers, 1926"; "Clinical Syphilology," by John H. Stokes; "Principles and Practice of Chemotherapy," by John A. Kolmer; "The Specialties in General Practice," by F. W. Palfrey and teachers of the Harvard Medical

School; "Health Supervision and Medical Inspection of Schools," by Thomas D. Wood; "Textbook of Clinical Neurology," by Israel S. Wechsler; "Diseases of Infants and Children," by J. P. Crozer Griffith; and "A Textbook of Medicine by 130 Authors," edited by Russell L. Cecil.—[70] John Smith and Son (Glasgow) Ltd. (26–30, Gibson-street, Hillhead, Glasgow), had on view, among other recent publications in all branches, Jacobi's "Atlas of Dermochromes"; THE LANCET volumes of "Modern Technique in Treatment"; and the Modern Medical Monograph Series, including Langdon Brown on "Endocrines" and a new edition of MacLean on "Renal Disease." They had also a number of early medical works.—[23] John Wright and Sons, Ltd. (Bristol), showed "Diseases of the Nose, Throat and Ear," edited by A. Logan Turner; "Synopsis of Physiology," by A. Rendle Short; "Cystoscopy," by J. B. Macalpine; and many other standard works; also "The Medical Annual" and the *British Journal of Surgery*.—[72] An innovation was the stand of H.M. Stationery Office, where were displayed the publications of the Medical Research Council, the Ministry of Health, and the National Physical Laboratory; also the medical history of the war and ordnance maps.

SPAS AND MISCELLANEOUS.

[3] At the Bath stand there were pictures of the spa and its therapeutic installations, and attention was drawn to the Old Royal Baths, to be opened in September, chiefly for intestinal douching and treatment in the pool.—[7] The Buxton exhibit consisted of photographs, guide books, and samples of the waters. The Corporation has taken over the Buxton gardens to run in connexion with the bathing establishment. The three-guinea-inclusive treatment scheme has been a great success.—[5] The Harrogate spa has many varieties of medicinal waters, under the constant supervision of a permanent scientific officer. Efforts are being made to popularise the sulphur water cure.—[75] The Stanboroughs, London Area Hydro, Watford, had a stand with illustrations of this country estate where treatment of all kinds is provided as at a hydropathic establishment.—[95] Droitwich claims that its unique brine baths are being more and more generally recognised. Accommodation has recently been extended and includes private and swimming baths, douche, needle, vapour, and aeration baths.—[55] Ingram and Royle, Ltd. (45, Belvedere-road, S.E. 1), as sole agents, were displaying samples of water from the three Vichy springs; Carlsbad waters and natural sprudel salt; and Hunyadi János, as well as many other natural mineral waters.—[79] The Hammond Varityper Co., Ltd. (75, Queen Victoria-street, E.C. 4), showed their instrument equipped with medical keyboard and demonstrated its ability to write any language in 360 different kinds of type with variable spacing, and to duplicate or cut stencils without extra effort. A portable model is made.—[111] The Royal Typewriter is also made in standard and portable models with a medical keyboard. Its colour can be selected to match the decoration of the consulting-room. The small pattern weighs 9½ lb. without case.—[66] The Museum Galleries (53, Short's-gardens, Drury-lane, W.C. 2) as usual broke the monotony of the strictly useful with a display of reproductions of old masters and portraits of medical men, including Lister, Simpson, and Harvey. They showed also a mezzotint of Dr. Harvey explaining the circulation to Charles I., directly engraved from the original in the Royal College of Physicians.—[108] Refreshingly unusual was the display by Sedley Rothwell (71, Oxford-street, W. 1) of hand-painted glassware and Italian Gesso work. The designs were exclusive and the paint would not chip or be damaged by hot water.—[113, 37] The Medical Sickness, Annuity and Life Assurance Society, Ltd. (300, High Holborn, W.C. 1), and The Medical Insurance Agency (B.M.A. House, Tavistock-square, W. 1) had their usual stands.

Reviews and Notices of Books.

INFECTIOUS DISEASES.

Ker's Manual of Fevers. Third edition. Revised by CLAUDE RUNDLE, O.B.E., M.D. Lond., M.R.C.S. Eng., L.R.C.P. Lond., D.P.H., Medical Superintendent, City Hospitals and Sanatorium, Fazakerley, Liverpool, and Lecturer on Infectious Diseases to the University of Liverpool. London: Humphrey Milford, Oxford University Press. 1927. Pp. 346. 12*s.* 6*d.*

THIS well-known manual of fevers, by Dr. Ker, of Edinburgh, was first published in 1911 and reissued in 1922. The present edition has been revised by Dr. Claude Rundle, of Fazakerley, who states in the preface that he has endeavoured to incorporate the results of recent research, keeping in mind the double purpose of the late Dr. Claude B. Ker—that is, to instruct students and to help practitioners. Dr. Ker was known to a generation of students as one of the greatest teachers of infectious diseases in this country and his gifts of clear exposition were well shown in this manual and in his larger work. Dr. Rundle has revised many chapters so as to include the recent work on scarlet fever, diphtheria, and measles. We note that a slight alteration in the antitoxin dosage is recommended, Dr. Rundle advising somewhat larger doses of diphtheria antitoxin than those formerly used. Dr. Ker was one of the pioneers in this country in the matter of the Schick test, and it is to the stimulus supplied by him that the success of immunisation against diphtheria among the school-children of Edinburgh is due. It is fitting, therefore, that this manual should continue to live as a faithful monument of his work.

Diphtheria, Measles, Scarlatina. Second edition. By FRANK V. G. SCOLES, M.D., B.S. Melb., D.P.H. Camb., Medical Superintendent, Melbourne Infectious Diseases Hospital. Melbourne: William Ramsay. 1927. Pp. 321. 21*s.*

THE first edition of this book appeared in 1919 and consisted of a number of lectures, slightly amplified and presented in book form. The present edition has been thoroughly revised and brought up to date. The book is mainly a record of personal opinions and contains much useful information. The author is a keen observer and has sound views on the treatment of these infectious diseases. He includes many useful tables, notably the scheme of antitoxin dosage in diphtheria; while the treatment of laryngeal diphtheria by intubation is admirably discussed. Recent researches on diphtheria and scarlet fever are fully described. There are no plates and no temperature charts, which would have been acceptable, but the book is, on the whole, well written and should prove of great value to the senior student and the practitioner.

DISEASES OF THE EAR IN CHILDHOOD.

Die Ohrenkrankheiten im Kindesalter. Second edition. By Dr. GUSTAV ALEXANDER, Professor of Otology in the University of Vienna. Leipzig: F. C. W. Vogel. 1927. Pp. 399. M.39.

THIS work first appeared in 1911. The second edition has been considerably enlarged; several sections have been revised, including those on the deaf child and the aural complications of general diseases, and a certain amount of new matter has been introduced such as the descriptions of latent otitis, mastoidismus and otitis interna vasomotoria. By the term mastoidismus Prof. Alexander means the symptoms of involvement of the mastoid in the first few days of an acute suppurative otitis, which symptoms retrogress and disappear by the end of the first week. In his view the pus which would be found in the mastoid cells at this stage has flowed into them from the antrum owing to the position of the head, without the cells

iemselves participating in the inflammation. It is, owever, equally reasonable to assume that the astoid cells are inflamed, together with the rest of ie auditory tract, in the early stage of an acute itis, but that they often tend to recover under the fluence of good natural drainage; it is unlikely iat the mastoid would be painful and tender if it ere merely the repository of pus from elsewhere. f the peculiarities of the ear of infants Prof. Alexander ghtly lays stress on the thick and resistant ear-drum young children, whereby an acute otitis may persist r one or two weeks without perforation. This factor, gether with the short and wide Eustachian tube, akes latent otitis far commoner in children than in dults. The infantile characters of the membrane, ie wide Eustachian tube, shallow tympanum, and nited pneumatisation are the anatomical basis of ie susceptibility to inflammation of the middle ear childhood. Of the effect of this last factor he gives ie following example. Suppose, as a result of disturbnce of function of the Eustachian tube, that 1 c.cm. air is absorbed, if with full development of the cells ie entire content be 6 c.cm., the pressure is only duced by some 17 per cent.; but if with deficient neumatisation the total capacity be only 2 c.cm., e pressure is reduced by 50 per cent. and a serious gree of negative pressure results. This argument surely unsound, for, with numerous air-cells, there ust be a large surface for absorption. For parantesis he advises local anæsthesia by means of stillation of a 20 per cent. watery solution of ovocain or alypin; in our experience this produces tle or no anæsthesia in an inflamed drum, and in this untry a general anæsthetic is almost universally referred. The same tendency is shown in the commendation of local anæsthesia for the removal adenoids; the removal of the faucial tonsils is not scribed, though very often necessary in the treatent of aural disease.

Much of the ground covered by this book is necesrily the same as that of any work on otology, for r diseases of children only differ in certain respects om those of adults; the chapters on congenital philis, tuberculosis, and on the aural complications the specific fevers are of special interest, and are ell and clearly written. The illustrations are good, pecially the plates of anatomical drawings, and the ork as a whole is well arranged and likely to be eful to all interested in children's ear diseases—that to all otologists.

ALARIA.

Its Investigation and Control, with Special Reference to Indian Conditions. By ROBERT KNOWLES, Major, I.M.S., Professor of Protozoology, Calcutta School of Tropical Medicine; and RONALD SENIOR-WHITE, Malaria Research Officer. Calcutta: Thacker Spink and Co. 1927. Pp. 220. Rs.78.

THE activities of the Calcutta School of Tropical edicine are not merely confined to research, but find itlet from time to time in the issue of useful volumes. he dedication "With respectful homage to the wives research workers in recognition of their sufferings the cause of Science" is not to be taken as an index iat the subject matter is handled flippantly. On ie contrary, the book is packed full of information of ie kind most valuable to the medical officer entrusted ith civic or rural sanitation in India. It is informave, too, on subjects which are not adequately mmarised in a convenient space in any other andard work. The book is divided into six chapters, which the first three deal with parasitology and icroscopic diagnosis; much of this information, as freely acknowledged, is based upon Wenyon's ork. In subsequent chapters the treatment of alaria, the carrying out of a malaria survey, and ie design, maintenance, and construction of antialaria measures are dealt with in a practical way. ppendices, among the most useful features of the ook, include notes on breeding-places and distribuon of Indian anophelines, illustrated with outline xt-figures of venation, markings, and larval characteristics. A note on technical specification for underground drainage and a useful bibliography complete the work.

The sections on the blood changes in malaria, methods of artificial culture of plasmodia, the measurements of the splenic index, and Sinton's alkaline quinine treatment are specially to be commended. The volume is well illustrated; the five plates of malaria parasites and blood cells are a trifle over-coloured, but this is a minor blemish.

THE NORMAL THYMUS.

Die Menschenthymus in Gesundheit und Krankheit. Vol. I. *Das normale Organ.* Second edition. By J. A. HAMMAR. Leipzig: Akademische Verlagsgesellschaft, M.B.H. 1926. Pp. 570. M.81.

THIS volume contains a detailed account of the author's own work. The greater part of the book is taken up with a detailed description, together with drawings to scale, of the numerous types of thymus gland, human and animal, fœtal and adult, that he has examined. The most interesting chapter of the book deals with status lumphaticus. The author maintains that the diagnosis of this condition depends not on the gross size or weight of the organ, but on the relative proportion of cortex and medulla. He complains that in the recorded cases of thymus death notice is only taken of the gross weight of the organ, and no account is given of the microscopical appearance. The literature is extensively reviewed. This book will be of interest to those attempting to study the curious phenomena said to be associated with the enlarged thymus.

THE LIFE OF THE SPIDER.

By J. HENRI FABRE. Translated by A. T. DE MATTOS. With a preface by MAURICE MAETERLINCK. London: Hodder and Stoughton. Pp. 288. 2*s.* 6*d.*

No one reads Fabre with indifference. To some people he is the most wonderful naturalist there ever was, and they read what M. Maeterlinck calls "the most extraordinary of tragic fairy tales" with a glowing enthusiasm. Others find him wearisome, and are irritated by his open contempt for any method of searching for the truths of biology other than his own. In any case, there is here provided an admirably cheap and well-printed edition of one of his best known collections which is convenient for the pocket and so for reading in the proper place—that is, out of doors.

TELEPATHY.

The Sixth Sense. By JOSEPH SINEL. With a Foreword by MACLEOD YEARSLEY, F.R.C.S. London: T. Werner Laurie. 1927. With three plates. Pp. 180. 6*s.*

THE author has for many years been interested in what are generally called "supernormal" phenomena, and he has been roused to put some of his experiences and convictions on paper by what he thinks is the quite unjustified scepticism which prevails pretty widely about the honesty of the facts. His most interesting data are a long series of experiments, spread over a number of years, in which he drew rough diagrams and pictures in secret which the other party, with no possibility of seeing the originals, reproduced with singular fidelity. The greater part of this might be simple telepathy, which he treats very shortly as a common fact of experience. But in some instances the form rather than the meaning was reproduced—e.g., a sketch of a nursemaid being led by a puppy on a string reappeared as a nursemaid wheeling a go-cart. From this sort of occurrence he concludes that not only the human brain but all matter gives off rays which can be perceived, without the intervention of any of the ordinary senses, by anyone who has the faculty of adjusting their mind to receive them. His arguments

for the existence of this clairvoyance are not altogether convincing; it is difficult, perhaps impossible, to be sure that telepathy is completely excluded. And his identification of the pineal body as part of the apparatus concerned is no more than an act of piety in memory of Descartes. We have more sympathy with his thesis that there is no need to invoke the existence of a spirit world to explain the phenomena: the other world to Mr. Sinel is here and now. He notes too briefly that telepathy and clairvoyance play a much larger part in animal than in human life: a more ample treatment of this side of the question would have been welcome from one whose accomplishments as a practical biologist were shown in the admirable "Natural History of our Shores" published about 20 years ago.

ORGANIC CHEMICAL ANALYSIS.

A Student's Manual. Reissue with Appendix on New Methods of Organic Analysis. By JOCELYN FIELD THORPE, C.B.E., F.R.S., Professor of Organic Chemistry, Imperial College of Science; and MARTHA ANNIE WHITELEY, O.B.E., D.Sc., Assistant Professor. London: Longmans, Green and Co., Ltd. 1926. Pp. 250. 9*s*.

THIS manual is a reissue of the book previously reviewed in our columns, with the addition of an appendix on New Methods of Organic Analysis by H. Ter Meulen and J. Heslinga. The incorporation, without any comment, of the work of these two Dutch chemists is a little surprising; the methods described have only been evolved during the last three or four years, and it is to be regretted that the authors do not bring forward any evidence of having tried these new methods themselves before recommending them to others.

THE SEX GLANDS.

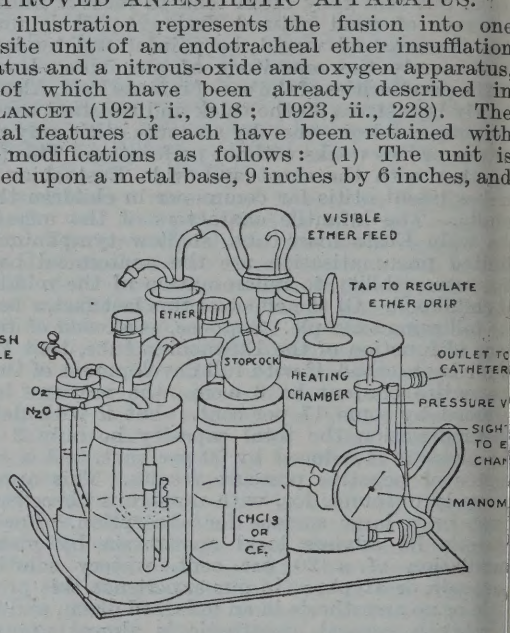
Die Wirkungsweise abgestufter Keimdrüsenschädigung. By Dr. H. V. KLEIN. Berlin: Urban and Schwarzenberg. 1927. Pp. 128. M.12.

THIS monograph contains a detailed review of the literature on the function of the sex glands and a very complete bibliography. The author also describes a number of experiments of his own on rabbits and guinea-pigs. The experiments can be divided into two main groups: (1) quantitative operations, such as castration and partial castration; and (2) qualitative operations, such as autoplastic transplantation, ligature, section or resection of the vasa, radium or X ray radiation, effects of heat and cold, effects of drugs and poisons, and temporary sterilisation with the cautery. Many of Dr. Klein's results are well in accord with those of other observers, but in certain points he differs from them. He finds that increase in weight and tissue-fat is not an invariable accompaniment of castration in the male, and even less so in the female. His quantitative partial castration experiments were inconclusive. In his autoplastic transplantation experiments in adolescent guinea-pigs an interesting finding was a remarkably rapid development of somatic and psychical sex phenomena. The animals were, of course, sterile, but, even after 12 months, evidence of development and maturation of sperm cells was obtained; but an increase in interstitial cells was not a constant finding. The endocrine effect in autoplastic transplantation rarely lasts more than a year in the male, but in the female the endocrine function appeared to last longer after transplantation than in the male. Much the same effect in the male was obtained by ligature of the vasa. In his X ray radiation experiments the author was unable to reach a dose which could in any sense cause a true "Rontgen castration." He found that radiating the ovaries of an immature rabbit led to destruction of part of the follicular apparatus; but the remainder became more active than before, and brought on premature sexual maturity. The interstitial cells were found to be more resistant to X rays than the glandular elements.

New Inventions.

IMPROVED ANÆSTHETIC APPARATUS.

THE illustration represents the fusion into one composite unit of an endotracheal ether insufflation apparatus and a nitrous-oxide and oxygen apparatus, both of which have been already described in THE LANCET (1921, i., 918; 1923, ii., 228). The essential features of each have been retained with slight modifications as follows: (1) The unit is mounted upon a metal base, 9 inches by 6 inches, and



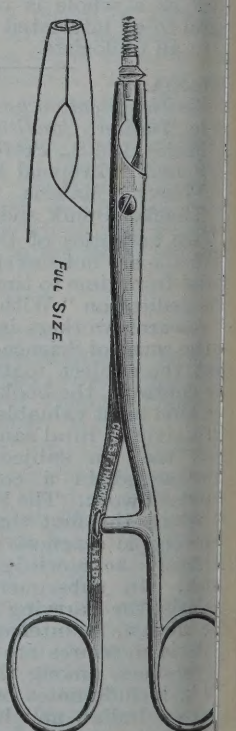
can be carried in a bag without being dismantled. (2) The mechanical safety-valve and manometer are now fitted directly on the heating chamber. (3) The ether drop-feed has been altered to the shape of a dome which can be easily seen from any angle. (4) A water sight-feed has been included for the administration of carbon dioxide.

The makers are Messrs. Down Bros., Ltd., St. Thomas's-street, S.E. 1.

I. W. MAGILL, M.B., B.Ch., B.A.O. Belf.

A SCREWDRIVER FOR OX BONE PLATES.

Cunningham's ox bone plates fixed with bone screws are now largely supplanting metal plates in the operative treatment of fractures. The insertion of a bone screw differs in several respects from that of a metal screw, the former requiring more finesse of technique. After the bone has been bored with a drill, the resulting cavity is "tapped." It is then ready for the reception of the bone screw. For the purpose of inserting the bone screw I have found the forceps-screwdriver of the greatest possible assistance. The readiness with which this instrument can be disengaged prevents the disappointment caused by the thread of the screw becoming broken in endeavouring to release the ordinary screw holder.



The instrument is made by Messrs. Thackray, of Leeds.

HAMILTON BAILEY,
F.R.C.S. Eng.

THE LANCET.

LONDON: SATURDAY, AUGUST 20, 1927.

THE METROPOLITAN ASYLUMS BOARD.

THE Metropolitan Asylums Board, which has just ssued an annual report [1] for the twenty-ninth year succession, may be regarded from the medical andpoint as a coördinated group of special hospitals; very large group, it is true, for the capital outlay own in the financial statement up to the end of arch, 1926, is given as over £7,500,000. The hospitals, should be well known by this time, include not ly 15 institutions for infectious diseases, but ten hers for tuberculosis, six for non-dangerous forms mental failure, five for sick and convalescent ildren, and one for venereal diseases. The funds for nning these very large and efficient hospitals which rve an area covering 121 square miles, with a popula- n of over 4,500,000, are raised principally from a vy on the rateable value of the area, which is pooled as not to press unduly on the poorer parishes and ions; to take an example, the rate is levied on value of £8,000,000 in the City of London, which s only an estimated population of 13,000 to make e of the hospitals, while in Wandsworth, which has rateable value of under £4,000,000, there are over 0,000 persons who stand to benefit thereby. Some dication of the return obtained for the money may gained from the statement that the treatment of ver uses up a rate of nearly 4*d.* in the £, tubercu- is and children each another penny, and the care imbeciles and feeble-minded persons just over 3*d.* ie Board's record of central efficiency and economy, ng with liberty for advance and healthy rivalry nong its several units, is worth the attention of ose who are sweeping away the Poor-law and all works. Etymologically it is interesting to see the rvival of the term "asylums" as a description of stitutions none of which deals with acute or ngerous mental disease, and it may not be too uch to hope that the beneficent and universally pular work of the Board may succeed in redeeming e term from the stigma of its association with rdship and restraint.

The development of the medical work has gone on interruptedly since the Board was established under e Metropolitan Poor Act of 1867, when the classes gible for admission were limited to harmless Poor- v imbeciles and Poor-law cases of scarlet, enteric, d typhus fevers and small-pox. Sixteen years later e civil disabilities attached to admission to the ard's hospitals were removed and year by year w categories of physical and mental diseases were ded to the eligible list. The year under review is table for the highest number of whooping-cough ses ever under the care of the Board at one time ice their admission began in 1910. On March 15th t 789 beds were occupied by cases of whooping- ugh of a character severe enough to make hospitalisa- n desirable, the justification for this allocation being shown by the level of the case-mortality in hospital of this so-called trivial childish affection, which has rarely sunk below 10 per cent.; whereas the percentage case-mortality from scarlet fever has steadily fallen from 12·6 in the 'eighties to less than 2 during the last ten years, and has actually been only 0·8 in the year under review. Approval has now finally been given to the limitation of beds for scarlet fever cases, to make room for severe cases of measles and other infectious diseases of childhood when accommodation is insufficient for all. Acting on the consensus of the metropolitan medical officers of health, the Board will continue to admit cases of scarlet fever and measles on practitioners' certificates as now, without reference to the medical officer of health, until such time as any shortage of beds is imminent. Should this occur, applications from practitioners are to be referred to the health office, when the selection of cases for admission will be based on type of home rather than on type of disease, priority being given to cases of measles in tenement houses where there are no facilities for home nursing, or in houses connected with shops, or where a member of the family is employed in the handling of food. These arrangements will require some extension in the facilities for isolation at the infectious hospitals, and on the advice of Dr. F. F. CAIGER, the retiring chief medical officer of the Infectious Hospital Service, the isolation accommodation in the acute hospitals is to comprise one-third of the total beds. Dr. F. H. THOMSON, the new chief, issues a word of warning against regarding the present benignity of scarlatina as permanent. The behaviour of this disease during recent years is not unlike what has happened in the past. It behoves us, he writes, to be on our guard and to perfect its treatment by antitoxin in every way we can, lest we be caught napping.

Change is also going on in the accommodation at the mental hospitals. An undertaking given by the Board to the London County Council to reserve 30 beds per month for suitable mental defectives has resulted in the exclusion of cases from outside the metropolis, although as a matter of fact the demand on the part of the County Council has been less than was arranged for. In general the admission of children to these hospitals continues to fall off, for the County Council now has its own special schools, and only after leaving these does institutional care become essential. Applicants for admission are therefore now generally young adults, and again it may be emphasised that these hospitals are designed for patients of harmless type, not for those who have come under the notice of the police. At the Darenth Colony the attempt to make these young people content with their new existence is successful with all except the most restless of the high-grade defectives. The facilities for schooling, for various kinds of manual occupation, and for the utilisation of free time by guide and scout activities, as well as more conventional forms of entertainment, fill up the day so pleasantly that parents, it is hoped, will come to regard the period of treatment no longer as a period of punishment. The mental hospitals, however, have to face a difficulty in the shortage of nursing, for although there is no general shortage of new probationers in the fever hospitals and no lack of male mental nurses, the supply of suitable female candidates for nursing is inadequate at three out of the five mental hospitals. The report suggests that the remedy lies in the acquisition of a reputation for giving an efficient training and for attention to the personal comfort which compensates the nurse for the restrictions inseparable from hospital life.

SUMMER DIARRHŒA.

THE problem of summer diarrhœa at one time perforce exercised the minds of all urban practitioners and medical officers of health, for the disease was often a calamity. Year by year, whenever the summer was hot and especially when it was hot and dry, there was a heavy toll of deaths, levied almost entirely on young children. The last great epidemic, however, was in 1911—a year in which the summer was hot and dry almost without precedent—and since then the incidence has rapidly diminished, becoming, indeed, comparatively negligible. In the first week of the present month only seven deaths were registered in London as due to diarrhœa and enteritis under 2 years. Considerable speculation centres round the reasons for this decline.

The belief that summer diarrhœa is an infective disease spread under certain climatic conditions led at one time to diligent search for the bacterial cause. The results were rather surprising, for in America *Bacterium dysenteriæ* was isolated in many cases, in France *Bacillus proteus* was advanced as the cause (though the evidence was very incomplete), in Germany other bacilli were found, whilst the careful work of MORGAN suggested that Morgan's bacillus was responsible in at least a considerable number of cases in English outbreaks. These conflicting results have thrown doubt upon the conception of summer diarrhœa as a disease with a single bacteriological cause in any way comparable with dysentery or enteric fever; indeed, there is some divergence of opinion whether it is a definite clinical entity. Of recent years considerable evidence has been put forward in favour of the view that the condition is of nutritional origin. According to this theory the prevailing ætiological factor is bad feeding, as a result of which diarrhœa and dyspepsia develop under the circumstances produced by a considerable rise in temperature. The immediate cause may be infection with bacteria already present in the intestinal tract or may possibly be chemical and fermentative disturbance. Many exponents of the widely held infective theory consider that flies play a conspicuous part, and the striking decline has been ascribed to the replacement of horse by motor traffic and the resultant diminution of centres of infection. Others ascribe much of the decline to improvements in the milk-supply and to the care of milk in the home.

The impartial student must admit that none of the theories fits all the facts, and we welcome a recent paper[1] by Dr. G. S. WILSON which attacks the problem from a different point of view. He describes two epidemics among mice that were closely associated with Morgan's No. 1. bacillus. In both of these epidemics the mice, which were fed on oats and raw beef, were found at autopsy to be suffering from peculiar lesions—an advanced degree of anæmia, pale and swollen kidneys, and general pallor and dryness of the tissues—not hitherto encountered in any other mouse epidemic. In other series of experiments the mortality from infection by Morgan's bacillus was much higher (12·9 to 1·9 per cent.) among meat-fed mice than among the controls. Dr. WILSON throws no light upon the factors which enable Morgan's bacillus to spread in epidemics among mice, and his attempts to infect mice by feeding them on cultures of this organism were ineffective. It appears that the bacillus can give rise to infection only in the presence of some predisposing factor, and it is possible that this factor may be dietetic. Summer diarrhœa in infants may be due to non-lactose-fermenting bacilli which are enabled to multiply and transfer themselves from case to case under certain conditions of which high temperature seems to be one of the most important.

MENTAL DISEASE IN THE LABORATORY.

THE awakening of interest in the physical pathology of mental disease marked a great step forward. Formerly, insanity was regarded as a psychological or spiritual anomaly, and the attempt to approach its mysteries through the study of the body was a sign of emancipation from fatalism. The spread of this movement has been rapid, and it has steadily coöpted neurologists, endocrinologists, and biochemists into its ranks. There has, in fact, even been a danger of a general drift away from the study of morbid pathology, as Dr. EDWIN GOODALL remarked in his Maudsley Lecture on May 19th.[1] He expressed the hope, however, that the active interest shown by so many workers in normal brain histology would save the morbid side from serious neglect, and was indeed, able to give several convincing examples of progress made in recent years. His survey of the fields of endocrinology, serology, and bacteriology shows how actively these are cultivated, but the most remarkable strides of recent years have undoubtedly been made in biochemistry. Prior to 1904, he said, he could recollect no outstanding communication from a chemist in the realm of psychiatry, but in that year appeared "Some Metabolism Studies, with special reference to Mental Disorders"[2] by FOLIN and SCHAFFER. This work led to the conclusion that general paralysis of the insane might be associated with metabolic disorder and that different abnormalities of metabolism occurred frequently in all types of mental patients, but pointed to the need for more accurate analytical methods before any definite coincidences could be proved. This was the borderland between pure chemistry and the much more complex and elusive biochemistry. Only those, says the lecturer, who have been in touch with biochemical investigation can appreciate the amount of spade-work that was necessary to evolve accurate methods, without which research could not begin. If biochemistry is to be really effective, its exponents must work in close association with the physiologists and biologists and with the clinicians and pathologists.

Here a good example is epilepsy. In our last issue (p. 325) the biochemical investigations of epilepsy were well summarised by Dr. S. H. G. ROBINSON, Dr. RUSSELL BRAIN, and Mr. H. D. KAY, who drew attention to the association of low blood cholesterol with the occurrence of fits. Dr. GOODALL points out that the assumption that hypoglycæmia precedes a fit has not been confirmed. Large doses of glucose did not affect the incidence of the fits in a series of epileptics. Nor is alkalosis a forerunner of the paroxysm, for dogs with epileptogenic lesions of the Rolandic area do not suffer from fits when the alkalinity of their blood is artificially raised to pH 7·50. The blood-sugar content of the blood of the epileptic does not tend to alter consistently either before, during, or after the fit; but the cerebro-spinal

[1] The Eighth Maudsley Lecture: Dealing with some of the work done to elucidate the pathology of disease falling to be considered under the rubric "Insanity," Journal of Mental Science, July, 1927. The Maudsley Lecturer for 1928 is Dr. John Macpherson.

[2] American Journal of Insanity, lx., lxi., 1903–1905.

gar is generally higher than that of the normal bject, and is raised slightly during a fit. General ralytics, on the other hand, usually have a lower rebro-spinal sugar content than normal; this ay be due to faulty functioning of the choroid exus or gland. Much work has been done on the nction of the choroid plexus with its cellular ing, which seems to be part of the "barrier" otecting the nervous system from the blood stream. the latter part of 1924, WALTER discovered a ethod of testing the degree of permeability of this rrier, by giving sodium bromide for three days and mparing the amount of bromide in the serum with at in the spinal fluid by a colour test. The result of is comparison is expressed in the form of a rmeability quotient (P.Q.), which in the normal rson varies between 2·90 and 3·30. WALTER and AUPTMANN have suggested that the P.Q. is high in hizophrenes and low in those suffering from functnal or symptomatic psychoses. BÜCHLER found the minished permeability of the screen more marked in unger schizophrenes. Dr. GOODALL, however, ds that this test will not serve as a means of diagnosis tween the two conditions. KANT observes a nnexion between increased permeability (a low Q.) and lability of the plasma colloid, and between high P.Q. and a stability of the plasma. The rmeability in general paralysis is high. A valuable scovery was that of the low sugar tolerance of ost early and chronic mental patients, especially ose suffering from melancholia and stupor. The sting level is normal, but the glucose meal leads to sustained hyperglycæmia. Dr. GOODALL considers at this may very likely be due to lability of the getative nervous system. In the normal person, mulation of this system leads to glycogenolysis rough a greater activity of the gastric mucosa; in gotonic patients it leads to a storage of liver gcogen. The lecturer also described the vast mount of careful work done on the calcium and osphorus contents of the body in various abnormal ntal conditions, and the proportion of the various rogenous constituents of the plasma and cerebronal fluid. The studies in the Acid Base Equilibrium Psychoses carried out by Dr. ISABELLA ROBERTSON (THE LANCET, August 13th, p. 322) while working at e Maudsley Hospital are typical of the kind of work hich should lead us to a better understanding of the ation of physical to mental abnormalities.

Psychiatry has passed through a superstitious phase d a materialistic phase. It is now in the fresh our of adolescence, and is undergoing sharp nflict between the claims of the speculative ychologists and those who seek to approach it m the physical side, of which the exponents are the chemical team. Happily, the balance is held by a ge number of far-sighted and able workers who ssess the application of the biochemists together th the vision of the analysts. The day may not be f off when the conflict will be resolved, and both es will work together to solve the deepest mystery medical science—that of human personality. Such bates as were held during the joint session of the urological and Psychiatric Sections of the British dical Association and the Royal Medico-Psychological Association form a good example of deliberate ack upon the problem.

NETHERLANDS INDUSTRIAL EXHIBITION. — This hibition, to be held at Rotterdam from June 1st to t. 15th, 1928, will contain a section on industrial welfare l psychology and occupational diseases. Exhibitors his section should apply to Dr. J. Sanders, Heemradssingel), Rotterdam.

Annotations.

"Ne quid nimis."

THE SEASONAL DISTRIBUTION OF MORTALITY.

WE have already called attention to some of the many points of interest in the Registrar-General's statistical review of England and Wales for 1925.[1] In our last issue appeared a note on the geographical study of mortality from respiratory disease. In past years the Registrar-General has published in his annual report some data concerning the seasonal incidence of the chief zymotic diseases based upon the death returns of London since 1841. In his most recent report appears a more ambitious and very important statement of the seasonal incidence of mortality from a large number of diseases, in regard to which improved accuracy has been secured by tabulating according to the date of death instead of the date of registration and by fusing the experience of the whole of England and Wales for the years 1921–25. The first curve given in the report deals with total mortality, and shows a maximum in February and a minimum in August. Its most remarkable feature is the disappearance of the former August rise, which was due to diarrhœal mortality. The standardised death-rate from diarrhœa fell by 27 per cent. between 1901–10 and 1911–20, and by 45 per cent. between 1911–20 and 1925. This important change to a single swing of mortality brings England into line with the general experience characteristic of Northern Europe; when the subsidiary summer elevation occurred England's experience resembled that of the middle and southern sections of Europe. The death curve follows fairly closely that of air temperature, and respiratory diseases are the dominant influence in bringing about the general effect. Some of the changes which are shown to have occurred in the seasonal incidence of infectious diseases have great epidemiological interest. The maximum of incidence of typhoid fever has shifted from November to October. Measles has ceased to have a double peak of mortality, and a special diagram shows the stages of the transition, as the result of which the December peak has disappeared and the June peak is replaced by one in April. Local variations in seasonal incidence of measles mortality were noted by the Registrar-General in 1884, and Prinzing records a remarkable change in the seasonal behaviour of measles in Hamburg during the nineteenth century comparable with that noted for London in the twentieth. Scarlet fever again has shifted its minimum from March and April to August and September, and its maximum from October and November to January. An interesting subject for speculation and still more for investigation is opened out by this change from the autumnal elevation, characterising typhoid fever and poliomyelitis, which has taken place in scarlet fever, and it may be added in diphtheria. A similar remark applies to measles. General interest attaches to the suggestions that the seasonal incidence in the mortality of gastric and duodenal ulcer and of heart disease—characterised by a marked excess at Christmas—may not impossibly be due to the excitement and over-indulgence in food which often occur at this season.

STUDIES IN SCARLATINA.

THE impulse which the recent work of the Dicks has given to research in scarlatina is reflected in the medical journals, and some exceptionally interesting developments are to be found in the current number of *Acta Pædiatrica* (Vol. VI., Fasc. 3–4) which contains three separate papers on scarlatina. In one of them, Dr. Malmberg and Dr. Jacobsohn, of the

[1] The first instalment of the Statistical Review for 1926 has now appeared (H.M. Stationery Office, 15s.). This contains Tables, Part I., Medical, without commentary.

Karolinska Institute of Stockholm, give an account of investigations with the Dick test in 1200 children attending hospital up to the age of 15. In infants of only six months the reaction was positive only in 16·4 per cent. This percentage had risen to 48·8 in infants between 6 and 12 months old, and the greatest proportion of positive reactions was observed between the first and fifth years. Thus between the years of 3 and 4 the percentage of positive reactions was 80·9. After the age of 6 there was a decline in the frequency of the positive reactions, the decline being at first slow and later more rapid. The supposition, credited to the Dicks, that persons who have had scarlatina give a negative cuti-reaction was not confirmed, at any rate as a generality. For among 802 children giving a positive reaction there were eight with a record of scarlatina. Among the 290 who gave a negative reaction there were 60, or 20·7 per cent., who had had scarlatina. Whether this negative reaction indicated a natural immunity or one acquired by an unnoticed abortive form of scarlatina is not clear. The consistency with which the reactions remained positive or negative when repeated once or oftener was investigated in many cases, and of 203 children giving a positive reaction on the first occasion as many as 190 did so on repetition of the test; only in two of these cases was the reaction definitely negative when repeated. Of the 82 giving a negative reaction on the first occasion, 54 continued to do so, and only in 17 cases did the reaction become positive. (It should be noted that in each series of tests there were some cases of doubtful reactions.) It would seem, then, that a positive reaction is a more constant and reliable phenomenon than a negative reaction. The paper by Dr. Gorter, Dr. Korte, and Dr. Munk includes an account of an epidemic of scarlatina in an asylum for mentally defective children. Of 74 boys, 22 suffered from scarlatina. Of the remaining 52, only 12 gave a positive reaction. Next day one of these 12 developed scarlatina. Of the remaining 11, six were given no specific treatment, yet some time later five of them were found to give a negative reaction, although in the meanwhile they had shown no clinical evidence of scarlatina. This observation would seem to indicate that immunity to scarlatina may be acquired by contact with it no symptoms are apparent. In the third paper Dr. Jundell and Dr. Lönberg, of the Karolinska Institute, give an encouraging account of 17 cases of scarlatina treated with antitoxic scarlatinal serum, obtained from a horse immunised to a toxin-forming strain of streptococcus from a case of scarlatina. This paper also contains a useful summary of the work already done in connexion with passive immunisation against scarlatina.

THE TREATMENT OF CATARACT.

"The verdict of the Indian peasant is destined to decide the treatment of cataract as it has decided that of stone in the bladder."

THIS is the dictum of Lieut.-Colonel Henry Smith, I.M.S. (retd.), whose own intracapsular operation is well known, and has created for him such a reputation in the Punjab that the number of operations performed in that province by his method has increased fourfold during the last 30 years. In the other provinces of India, where capsulotomy is practised, the figures have remained comparatively stationary.[1] How is it that in this country no intracapsular operation for cataract has as yet been established in the practice of the great majority of ophthalmic surgeons? The advantages are obvious. No soft matter and no capsule can be left in the eye to cause subsequent irritation and to obstruct vision. If the operation goes well the eye is as good as any eye without a crystalline lens can be. On the other hand, there are certain disadvantages. Whichever of the two principal intracapsular operations—Smith's or Barraquer's—is chosen, there is always the danger that in unaccustomed hands vitreous may be lost. How serious a slight loss of vitreous may be is a matter on which there may fairly be a difference of opinion, but there can be no doubt that a considerable loss is dangerous for the future of the eye. It is acknowledged on all hands that the results of an intracapsular operation in the hands of Smith himself, or Barraquer himself are excellent. The success of both operations depends upon the rupture of the suspensory ligament which normally keeps the lens in its place; this rupture has to be done by the exercise of just the right amount of force, for if too much is used there may be a large loss of vitreous. Smith's technique depends upon the pressure of a squint-hook on the external surface of the cornea, while the lids are kept apart by a skilled assistant to avoid the pressure of a speculum. Barraquer uses a special instrument by which a vacuum is created and the lens is drawn out. Smith, however, maintains, in the article already referred to, that Barraquer does, in fact, exercise pressure with his instrument, and that the actual technique of Barraquer's successful operations is analogous to that of his own, and that the reason why so many who have tried Barraquer's method have failed is simply that they have not understood this fact. This is not the place to describe the details either of Smith's or Barraquer's technique. Colonel Smith looks forward to the day when the capsulotomy operation now in vogue will be relegated to the dust-heap. Nevertheless, there is something to be said for conservatism in this matter. Before the majority of ophthalmic surgeons will adopt either of the new methods it is not enough to demonstrate to them many brilliant successes. They must also be assured that the small percentage of complete failures that even the best of surgeons must expect to meet with during his operative career is not in danger of being made less small. Without that assurance no new operation has a chance of being generally adopted in this country.

[1] Indian Medical Gazette, March, 1927.

TUBERCULOSIS IN THE FRENCH MERCHANT MARINE.

THE Superior Council of the Merchant Marine impressed with the prevalence of tuberculosis among the personnel of the French Merchant Service. Dr. Marcel Clerc, who is a member of the Council and has had large experience of the sea in mail steamers, can give no statistics[1] although he has part of the evidence before him at a tuberculosis dispensary in the Department of the Seine. Dr. Clerc assumes rather airily that things are better in England and Germany than in France, and he quotes certain pre-war figures from large French shipping companies which suggest a death-rate from tubercle among the sailors at that time of 0·9 per 1000. He then sets himself to discover what can best be done. Tubercle has been ascribed to poverty, bad housing, and drink which France cannot delay to put right, but there must be an element of infection too, resulting in the relapse of an old or the occurrence of a new infection and the first practical step must be therefore to exclude infection from all ships and fishing boats. The 1921 Congress of Hygiene at Paris resolved that no sailor with open tuberculosis should be allowed to join any boat or ship, and that the provision of cubic space and ventilation should be more generous. The first measure ought to be more effective in France than in England, for French seamen, being registered in the *Inscription Maritime* that they may be called up in war, are all known to the authorities. But this resolution has remained apparently a pious hope, and Dr. Clerc demands that all seamen shall be examined medically on entering the service and again each time on joining a new ship, and any who are found to be expectorating tubercle bacilli shall be rejected and ordered to the local tuberculosis dispensary for appropriate treatment and the care of their families.

[1] La Tuberculose dans la Marine Marchande. By Dr. Marcel Clerc, Member of the Superior Council of the Merchant Marine. Paris: Vigot Frères. 1926. Pp. 64. 1s.

is done for civilians in general. Fortunately, there in France a fund which pensions seamen, when capacitated by accident or disease, if these are rtified by their captains as caused by duty; and, fact, 37 per cent. of the pensions granted at Dunkirk 1920 were for phthisis. Pensions out of funds for ilors should, however, only be granted to men who ntract disease as sailors—that is to say, men certified und when they joined the service. This is the ocedure of all the large employers of labour in ance; they accept no new employees unless declared edically fit. At present tuberculous seamen are ly excluded from ships trading to the U.S.A., asmuch as an infected seaman involves the ship in avy expense at an American port. Dr. Clerc has idently given much time and thought to this estion of the prevention of tuberculosis at sea, and s careful studies should bear fruit in time. Tubercu- is has been halved in the British Navy in the last years, and, perhaps because of more careful edical examination and better hygiene, apparently the British mercantile marine as well.

MEDICAL OFFICERS UNDER THE POOR-LAW.

FOR some time past a Joint Committee of both ouses of Parliament has been considering a Bill ich has for its object the consolidation of all the or-law statutes relating to the relief of the poor. is Bill received the Royal Assent in the session st closed, under the title of the "Poor-law Act, 27." The Act commences with the famous Poor lief Act passed in the reign of Queen Elizabeth and ds with the Act passed last year. In view of the gth of time covered and the numerous statutes ich have been passed (some of them in conflict th one another, whilst others have become obsolete olly or in part), it may be useful to see what is the sition of medical practitioners under the Poor-law it stands to-day.

In the first place, we may classify Poor-law medical icers into two classes—viz., indoor (which does not cessarily mean resident) and outdoor. Indoor icers are appointed either to a workhouse (or nstitution" as it is more generally termed), an irmary or hospital, children's homes, or casual rds. Outdoor medical officers are appointed for specified district to attend to poor persons living their own homes. In the Metropolis medical icers may be appointed to dispensaries at which sons, who are provided with an order from a lieving officer, may receive attention.

Tenure, or continuance in office, of medical officers regulated by Orders of the Minister of Health or predecessors. Article 1 of the Medical Appoint- nts Order, 1857, prescribes that a workhouse dical officer

"shall hold his office until he shall die or resign or be proved to be insane by evidence which the Poor-law Board shall deem sufficient, or be legally disqualified to hold such office, or be removed by the Board." (The Minister of Health is now substituted for the Poor-law Board.)

In the case of infirmaries or hospitals and children's homes, as also of institutions provided by joint committees for feebleminded persons, and the like, special orders are issued by the Minister. The foregoing observations apply also to outdoor (or district) medical officers; indeed, there is no reason why the two appointments should not be combined. Although guardians have the right of appointing a medical officer, they have no power to dismiss him (though they can suspend him). The Minister will only accede to the guardians' wishes when the amount of compensation has been mutually agreed between them and the officer. Under the Poor-law Officers' Superannuation Act, 1896, guardians are empowered, with the sanction of the Minister, to pay an amount not exceeding twice the preceding year's salary and emoluments. The medical officer has also a statutory right to the return of the amounts deducted from his salary under that Act. If the Minister thinks it expedient for the purpose of improving the classification and management of any classes of poor persons that a resident medical officer should be appointed for any Metropolitan workhouse, he can determine or vary any officer's contract and direct the board of guardians to pay compensation by way of increased salary or otherwise.

Under the Poor-law Act, 1927, the Minister may:—"by order, either upon or without any suggestion or complaint in that behalf from the Board of Guardians remove, or suspend, any paid officer of the Board whom he considers unfit or incompetent to discharge his duties, or who at any time refuses or wilfully neglects to obey and carry into effect any rules, orders, and regulations made by the Minister. . . . Any person so removed or suspended shall not be competent to be appointed to, or to fill any paid office connected with the relief of the poor in any Poor-law union except with the consent of the Minister."

This section of the Act purports to bring the law into line with the existing practice. Under the statutes previously in force an officer who had been removed from one union could legally be appointed in another union, but the practice has always been to construe the statute as meaning that such an officer is ineligible to serve in any union unless the Minister assents thereto. The power of the Minister as regards removal is far-reaching. In the evidence given before the Joint Committee it was stated by a witness that he hesitated to say how often the Minister exercised the power of removal, but that he would not be surprised if there were four or five cases in each year of complaints.

The power of the Minister came before the Courts on two occasions—viz., in *ex parte* Teather (1850) 19 L.J.M.C. 70 when it was held that a relieving officer could be removed by the predecessors of the Minister although no charge had been alleged against him; neither had he been given notice nor given an opportunity of making any defence. So also in *ex parte* Molyneaux 7 L.T. 599 it was decided that a chaplain (who has the same tenure of office as a medical officer) was removable as unfit for his office and that no grounds need be assigned for such removal.

The Act makes no change in the duties of medical officers. These duties are prescribed by the Minister under his general statutory powers and they are contained in the General Orders. The main duties of a workhouse medical officer are contained in Article 59 of the Poor-law Institutions Order, 1913; those of the district medical officer are contained in Articles 198–200, 205–206 of the General Consolidated Order, 1847, as amended by the General Order of 1879, and the Powers of Guardians Order, 1921. Under the latter Order a district medical officer is allowed to live outside his district if no suitable medical practitioner resident in the district is willing to act at a reasonable remuneration. The Act re-enacts the duty of a workhouse medical officer, after examination, to report in writing whenever any inmate is not in a fit state to leave the workhouse without danger to himself or others by reason of suffering from delirium tremens or from bodily disease of an infectious or contagious character. The guardians may give effect to such certificate by requiring the master of the workhouse to detain such inmate until such time as the medical officer certifies in writing that discharge may take place. The parent or next-of-kin may, however, give an undertaking to provide for the removal, charge, and maintenance of such inmate with due care and attention while the malady continues, and in that case the inmate must be discharged. It has been held by the law officers of the Crown that an inmate suffering from venereal disease cannot be compulsorily detained under these provisions, nor apparently can cases of pulmonary tuberculosis be so detained. As regards the introduction of intoxicating liquors into a workhouse, this is prohibited by the Act unless for the domestic use of the officers. If such liquors are otherwise required, the medical officer or the guardians must give a written authority to the master.

The provisions in the Act relating to Metropolitan dispensaries re-enact the existing law. It is, however, provided that the dispensary committee is to appoint the district medical officers. As the dispensary committee may be composed of persons who are not

members of the board, it is the practice for boards of guardians to make such appointments themselves, and no doubt they will continue to do so, despite the statutory rule. For the purpose of establishing dispensaries in London, the Minister has power to vary medical districts and the salaries and contracts of district medical officers. Another provision, which applies only to London, is that boards of guardians, with the consent of the Minister, may enter into arrangements with any public general hospital or dispensary situate within the union, for the reception and treatment of persons in receipt of relief, on terms to be arranged between the guardians, with the Minister's sanction, and the authorities of the hospital or dispensary.

In conclusion, it may be pointed out that the Act does not extend to the Lunacy Acts, the Vaccination Acts, Registration of Births and Deaths Acts, or the Poor-law Officers' Superannuation Act.

C.S.M.M.G.

THE Chartered Society of Massage and Medical Gymnastics would have it known that anyone who is entitled to add to his or her name the initials C.S.M.M.G. has been through a supervised course of training and has passed a professional examination of high standard. After these conditions have been satisfied, no certificate of membership in the Society is granted until an undertaking has been signed by the applicant to observe the three rules which follow :—

(1) Not to undertake any cases of massage except under the direction of a registered medical practitioner.

(2) Not to advertise except in recognised medical and nursing papers.

(3) Not to sell goods to patients in a professional capacity, and not to accept secret commissions on the sale of goods.

The undertaking not to advertise has, we are told, been loyally obeyed, although at times it places the qualified masseur or masseuse at so great a disadvantage when competing with the unqualified as to suggest a doubt as to its fairness. But whenever the question has been raised the council of the Society has held that public advertising would be derogatory to the profession of massage, and the undertaking still remains obligatory on entrants. There are now over 5500 masseurs and masseuses registered with the chartered Society. The majority of these are qualified to administer remedial exercises and medical electricity, and the register shows that the members are well scattered over the United Kingdom and the dominions overseas. An illustration is given in the prospectus now in circulation of the extent to which physical treatment is employed in the larger London hospitals. Among male patients between the ages of 16 to 70 at two of these, 10 per cent. received during the year treatment involving massage, exercises, or electricity, the number of individual treatments per patient averaging 25. The Society, which was incorporated in 1900 and revivified in 1920 by amalgamation with the Manchester Institute of Massage and Remedial Gymnastics, has an advisory committee containing the names of ten representatives of the medical profession. Standing for the same ideals of professional education and social service as does the medical profession itself, the Society appeals to physicians and surgeons to employ only those who have the right to subscribe themselves C.S.M.M.G. And the appeal seems to us fair and reasonable.

THE DEFENCE OF MEDICAL RESEARCH.

THE past year has seen a spirited assault on experimental medicine by antivivisectionists of various complexion. The newspapers have been full of letters from people with hazy views on medical progress and a warm sympathy with animals ; the false conception of vivisection as torture has induced several hundred thousand of our countrymen to sign petitions in favour of a Bill exempting dogs from experiment ; and the Royal Society for the Prevention of Cruelty to Animals has only just been saved from using its important influence in the same direction. Whilst we are confident that medical research has nothing to fear from an instructed public opinion, it is clear that ignorance falls an easy prey to sentimentalism and inaccurate statistics, and the necessity for experiment on animals needs reiterated explanation at the present time. Many Members of Parliament, themselves uninterested in the subject, have unwisely pledged their support to measures for the limitation of research ; the funds at the disposal of antivivisectionist societies are apparently considerable, and the different arguments against animal investigation are put well enough to convince many sorts of well-meaning people. Opposed to all this we have the general consensus of the medical profession, and the work of one small organisation which aims at influencing public opinion, the Research Defence Society. The profession, as a whole, though in favour of experiment, is somewhat indifferent to the controversy, having other things to think about ; the Research Defence Society has a small membership and therefore small resources. As Lord Dawson has pointed out it is the public that would suffer from a veto on vivisection and it is for the public to decide ; but the profession has a duty to declare its opinion and it is much wiser to strengthen the defence mechanism now rather than wait until the infection of sentimentalism has got a real grip of the community. The Research Defence Society describes itself as "a national society of men and women united to promote national health and efficiency, to bring about a better understanding of the value of medical and surgical studies and to expose the false statements which are made against them." As such it must appeal to public-spirited medical men, and as we have said before it should have a membership as wide as the Medical Register. Naturally the subscription to a propagandist body cannot be nominal, but it is small. Five guineas brings life membership ; members subscribe 10*s.* ; associate members 5*s.* ; whilst undergraduates or students are eligible for membership at 2*s.* 6*d.* a year. The journal of the Society, entitled *The Fight Against Disease*, may be had from the Secretary at 11, Chandos-street, London, W. 1.

FLEXNER DYSENTERY TREATED BY THE BACTERIOPHAGE.

THE use of the bacteriophage as a therapeutic agent has given rise to much debate. D'Herelle has advanced large claims for its utility in such infections as typhoid and dysentery, and it has also been employed in the treatment of septic conditions. The results reported by others, however, have not borne out the claims of its discoverer, although in other fields his extensive work has been very generally confirmed. It seems probable that if the agent is capable of being employed for the active destruction of bacilli in the body its activity should be especially obvious in such a condition as dysentery, in which the disease is local, the organisms do not invade the tissues to any marked extent, and the bacillus is one upon which the bacteriophage has a marked effect. We have recently received from the Malay States [1] a report of the treatment of 22 cases of Flexner dysentery by bacteriophage which was provided by d'Herelle himself, and therefore may be considered authentic and of undoubted activity. Dr. W. Fletcher and his collaborator state that dysentery is one of the three most deadly diseases in the Malay States—the other two being malaria and tuberculosis—and it may be taken that those are sufficiently well versed in the vagaries of the malady to be good judges of the usefulness of a new form of therapy. Their investigation [1]

[1] The Bacteriophage in the Treatment of Bacillary Dysentery of the Flexner Type. By W. Fletcher and K. Kanagaray. Bulletins of the Institute for Medical Research, Kuala Lumpur, Federated Malay States. No. 3. 1927.

iem to the conclusion that the treatment "had no ›parent influence upon the course of the disease ıe to this organism, nor did it eradicate the bacilli om the intestines of those to whom it was lministered." Three tubes of the bacteriophage were lministered orally, with an interval of 12 hours ›tween each dose; in some cases a second course as given. A daily bacteriological examination of ıe stools was made to observe any effect produced ; the treatment in causing disappearance of the ıcilli. Apparently there was no such effect; the ganisms remained present as long in these cases in controls not treated by the method. These sults accord with those of other observers. They e not, however, quite so clean cut as to condemn e bacteriophage out of hand as an impotent agent, ıd we should be glad to see an extended test of e treatment made by independent workers over ntrolled series of cases of acute bacillary dysentery, ing a bacteriophage of maximum activity for the ecific type of infection present. This should be ssible in a country such as Malaya, where the sease is exceedingly common.

THE BRITISH ASSOCIATION.

THIS year's annual meeting of the British Association r the Advancement of Science will be held at Leeds ıder the presidency of Sir Arthur Keith, conservator the Museum of the Royal College of Surgeons of ngland. The title of his address, which will be elivered in the evening of August 31st, is Darwin's heory of Man's Descent as it Stands To-day, and is, like other subjects to be considered, is likely arouse much interest among the general public, whom the proceedings of the Association are ›wadays reported at considerable length by the news- ıpers. The annual meeting has in fact two important nctions; it stimulates the curiosity of the masses ıd it gives an opportunity for scientific workers meet each other. Members of the Association who e not specialists and who wish to acquire general formation have once again an immense choice set fore them, but the days have gone by when a person average attainments and education might expect to derstand and enjoy the discussions and papers most of the sections. Though medicine does not ure in the programme there will be a large number papers on physiology, psychology, education, and her related subjects, and among the presidential dresses to sections will be those of Dr. C. G. Douglas the development of human physiology, and of . William Brown on mental unity and mental ssociation. Dr. F. A. E. Crew is to give an evening scourse on the germ plasm and its architecture, d a discussion on the chemistry of hormones will opened by Prof. G. Barger, Prof. H. S. Raper, r. F. H. Carr, Prof. J. C. Drummond, Prof. E. C. ›dds, and Prof. J. Mellanby. A paper on the effect mental stress on man will be contributed by Prof. S. McDowall; Dr. D. N. Buchanan will deal with e psychological effects of flickering light; Dr. W. Edridge-Green will read two communications colour-blindness; Dr. A. H. Mumford will discuss dy measurements and respiratory tests in connexion th the progress of school-children; whilst Dr. D. Gillespie will give a paper on the estimation character and temperament in the light of psycho- gical medicine. As is natural, there are to be many ntributions on biochemical subjects. Dr. W. Cramer ll speak on the requirements of the population in lk-fat (vitamin A) and the available supply; lonel C. J. Bond on the effects of some radiated d non-radiated stearols on the cellular constituents the blood; and Dr. E. R. Dawson and Mr. B. S. att on the action of pancreatic lipase. Among the any topics of more popular interest are the physical periority of the so-called uncivilised races, the ychology of special scholastic disabilities, "the portance and value to the Empire of the trans- ıntation of boys," the control of plant diseases, and school examinations. Mr. H. R. Silva will speak on the experimental control of introspection, and Mr. L. Wynn-Jones on the appreciation of wit. The relentless march of specialism is illustrated by the fact that the programme does not allow those who are interested in Mr. Wynn-Jones's paper to hear the observations of Dr. Marion Hirst and Dr. C. G. Imrie on the excretion of creatine.

B.C.G. VACCINE.

DURING the last two years we have frequently[1] referred to the work of Prof. A. Calmette, of Paris, who recommends general protection of children against tuberculosis by means of the vaccine B.C.G. The letters C and G in the name of this vaccine stand for Calmette and Guérin, who are responsible for its introduction, whilst the letter B stands for *bilié*, and refers to the method by which it is prepared. Tubercle bacilli are grown over a period of many years on glycerinated ox bile, and this medium so reduces their virulence that living cultures are apparently harmless even to newborn infants when given by the mouth. According to Prof. Calmette and his colleagues, three doses of such a culture given to children in the first fortnight of their lives —i.e., before they have been infected by other tubercle bacilli—produce a high degree of immunity against later infection by tuberculosis.

Not long ago we briefly reviewed [2] the evidence in favour of this important claim, and pointed out that more work must be done before it could be accepted. It may be of interest, therefore, to give a brief description of an independent investigation conducted at Barcelona by Prof. L. Saye [3] and other members of the medical faculty. Their preliminary communication records the results of treating 134 infants with B.C.G. vaccine given in milk by the mouth within 14 days of birth; it is stated that 203 children were actually treated, but many were lost sight of, and in other cases insufficient time had elapsed to allow of conclusions being drawn. The remaining 134 cases they divide into two groups: (*a*) 113 in which the infants were brought up in an environment known to be tuberculous, and (*b*) 21 in which no such contagion could be found. The total number of deaths was 26, giving a mortality of 15·7 per cent. in the (*a*) group and of 3·7 per cent. in (*b*); but of these 26 infants only eight died of tuberculosis or of infection that was probably tuberculous. The actual mortality from tubercle thus appears to have been almost exactly 6 per cent., though the figure is not definitely stated. Having regard to the difficulty of excluding the presence of tuberculosis in infants clinically, the death-rate probably offers the best available evidence, and these figures appear to be favourable. But unfortunately Prof. Saye and his colleagues present their figures in such a manner that it is difficult to arrive at definite conclusions. There are numerous tables showing the relation of an affected father, mother, or other relative to the degree of infection and demonstrating other points of interest, but there is none which shows at a glance the actual effect of the inoculation with B.C.G. vaccine. This would be regrettable but for the fact that the experiment as a scientific test was vitiated at the very beginning; the investigators state that whenever it was necessary they tried to ameliorate the condition in which the vaccinated infant lived, and that they removed those whose parents were gravely infected. Their inquiry, therefore, gives no information about the value of this vaccine in protecting infants who are living in ordinary slum conditions; it is admitted that hygienic measures alone can greatly reduce infant mortality from tuberculosis. All that can really be deduced from the facts given is that Calmette's vaccine, whether given by the mouth or hypodermically

[1] THE LANCET, 1925, i., 1352; 1926, i., 1046.
[2] THE LANCET, 1927, i., 936.
[3] Revista Medica de Barcelona, March, 1927.

(in a few cases) is quite innocuous, and that when its administration is combined with hygienic measures and with removal from sources of infection there is a considerably reduced mortality. It remains doubtful how far this result is due to each of the three factors.

THE ULTRA-VIOLET RAYS OF SUNLIGHT.

SOME interesting data have recently been collected illustrating the seasonal variations of the ultra-violet component of sunlight in Chicago. In a short communication to the *Journal of the American Medical Association* for July 16th Dr. Herman N. Bundesen and his co-workers give the results of systematic spectrographic records of the sun's rays for the period November, 1926, to May, 1927. The daily records obtained from plates taken with a diffraction grating compare very closely with those of the quartz spectrograph, and both are employed to illustrate the seasonal variation in the ultra-violet value of sunlight and to emphasise the screening effect of a smoke pall in cutting out the biologically active rays. In view of the work of Hess and Weinstock, who have shown that 3130 A.U. is the longest wave-length of antirachitic value, while the maximum of potency lies at 3020 A.U., it is interesting to note that from November to February only a low intensity of the region 3130–3030 A.U. was observed, while no rays shorter than 3030 A.U. were recorded for the same period. From this it would appear that the sun's rays during the winter are of no antirachitic value, and this is in agreement with clinical experience. From February onwards steady improvement was noted, and on May 16th 2990 A.U. was registered as the short wave-length limit. In considering possible substitutes for sunlight during the dark months the writers draw attention to the incandescent filament lamp as a source of near ultra-violet rays. The biologically active rays from 3100 A.U. onwards emitted by filament lamps are quenched by a glass bulb, but this can be avoided by making the bulb of quartz or vitaglass. In studying the properties of the latter and similar glasses, the writers confirm the findings of the Council of Physical Therapy (noted in THE LANCET of August 6th, p. 316) to the effect that vitaglass is almost completely transparent to the ultra-violet rays of sunlight. Vitaglass with a transmission spectrum extending to 2760 A.U. is evidently an efficient substitute for quartz in any work in which sunlight or the incandescent filament lamp is the source of ultra-violet rays.

OUR readers will regret to learn that Mr. Alban Doran is suffering from acute glaucoma, and is at present a patient in St. Bartholomew's Hospital, under the care of Mr. Foster Moore. His sight has been failing for time some—a calamity for anyone, but particularly for so active a student as Mr. Doran has been ever since he entered St. Bartholomew's Hospital almost 60 years ago. Even when he retired from active consulting practice in 1911, and had earned a well-merited rest, he returned to the Museum of the Royal College of Surgeons, where, as a young man, he had assisted Sir William Flower and afterwards Sir James Paget. He then devoted himself and his ripe scholarship to various voluntary tasks. He drew up a new catalogue of gynæcological specimens, and afterwards undertook and completed a descriptive catalogue of the great collection of surgical instruments and appliances preserved in the Museum of the College, a task which occupied him for 12 years. No one has worked for his profession more industriously and less selfishly than Mr. Doran, and we are glad to know that his old hospital is doing everything for his comfort and recovery.

TUBERCULIN DISPENSARY BENEVOLENT SOCIETY.—Patients may be sent to the Tuberculin Dispensary at 32, Fitzroy-street, W. 1, for consultation and treatment on Tuesdays and Fridays at 2.30 P.M. Medical men are invited to attend.

Modern Technique in Treatment

A Series of Special Articles, contributed by invitation on the Treatment of Medical and Surgical Conditions

CCXXXVII.

THE TREATMENT OF SINUSES.

II.* SINUSES IN SPECIAL SITUATIONS.

The Frontal Region.

HEAD sinuses in the frontal region are ofte associated with infection of the air sinuses, whe the treatment of the latter is the primary considera tion; this also applies to sinuses over the mastoi Sinuses elsewhere on the skull, especially those ov the frontal region which are higher up than th situation of the air sinus, may result from a specifi infection in the form of a gummatous inflammatio with necrosis, and in these days this possibilit is apt to be overlooked. When specific diseas is the cause the sinuses readily yield to th appropriate treatment for that condition, and d not require local intervention. If the discharge fro a sinus on the cranium is noticed to pulsate, it wi probably be an example of extradural abscess whic has found its way to the surface spontaneously bu has not sufficiently drained.

The Jaws.

Sinuses about the jaws are nearly always caused b pathological conditions of the teeth. Even whe these appear normal they ought to be suspected, an should be carefully examined and finally X raye More than once a tooth has been sacrificed and sinus cured when the dental condition was reported t be above suspicion. A tooth which becomes loose fro time to time or has been previously injured is often dead one, and keeps up an infection around the ro which in turn may be the cause of a sinus. Even the mouth is edentulous the jaws should be careful X rayed, since fragments of teeth buried and lo forgotten may yet be the cause of so much infectio as to give rise to a sinus. Unerupted wisdom teet may also be associated with inflammatory troub followed by the development of an external sinu

When a tooth is the cause of a sinus, the latt almost always heals as soon as the offender h been removed, irrespective of the duration of th sinus, which may have existed for years. If th correct tooth has been extracted and the sin persists for longer than a week or two it may be wi to explore the socket with a sharp spoon, f occasionally bone débris may be keeping up t infection. If a tooth is not the cause, a sequestru is almost sure to be so, and will probably be easi detected on examination of the infected socket, will be seen by the X ray. Tubercle and actin mycosis both occur in the jaws and may be the cau of sinuses, but neither is common in this situation.

The Neck.

In the neck sinuses are most often associated wi broken-down tuberculous glands, and are commone when the gland is deeply situated beneath t sternomastoid muscle. Such cases illustrate t general problem of sinuses due to tubercle. The ide treatment is to remove the focus, and if the group glands is localised, and presumably infected from t tonsil or nasopharynx, their removal by a we planned dissection is the method of choice. Lon standing sinuses are apt to be secondarily infecte and an operation which will open up fresh cellul tissue must not be undertaken until an attempt h been made to diminish such secondary infection careful and repeated dressing with a reliable antisepti for this purpose the 1 in 1000 perchloride of mercu is the best. When it is not deemed expedient excise the focus with the sinus, the judicious use the sharp spoon will be most helpful, but t

* General Considerations in Treatment of Sinuses appea last week.

ject in view should be to scoop out the tuberculous oris at the bottom of the sinus, and not merely to ape the track itself. When local interference is not ntemplated, the general principles in the treatment surgical tuberculosis must be conscientiously ried out—namely, rest, abundant food, fresh air, l sleep. Multiple tuberculous sinuses in the neck nish the most promising field for light therapy.

Sinuses resulting from vestigial remnants such as thyroglossal duct and the branchial clefts are en very small, but are in characteristic situations, l at some stage clear mucus escapes even though other times the discharge is purulent. For their e operative interference is essential.

Sinuses Connected with the Joints.

n the neighbourhood of joints tuberculous sinuses common. Here the treatment merges into that tuberculous joints in general; but I must insist the importance of prolonged rest, for it is the tinuity of the treatment rather than the method ich is likely to lead to success. For tuberculous uses in general the best local application is pure bolic acid, which can be applied on a probe, after ich the orifice of the sinus is plastered with a te made of iodoform mixed with 1/1000 perchloride mercury in watery solution. The application uires to be made every week or ten days, and the atment by rest is to be continued indefinitely. y few tuberculous sinuses will refuse to heal if treatment is sufficiently prolonged. It is in these es, however, that adjuncts such as artificial light, the injection of Beck's paste, and so forth most useful. Personally, I have always been ner chary about using vaccines, but if sinuses those under discussion have resisted treatment for g, then a judicious use of a vaccine may just happen start curative processes which might otherwise indefinitely delayed.

Sinuses in the course of the long bones are usually result of sequestra, and these must be localised, ntified, and removed. Very small sequestra may always be clearly seen on X ray photographs; usually those that do not show will be safely uded by natural processes. When such tiny uestra are suspected it is a good plan to lore the sinus occasionally with a probe, for this ns up the track and is often followed by the rusion of the reluctant piece of dead bone.

Sinuses about the chest are most commonly due to ealed empyemata, but they may be from erculous foci in connexion with the ribs, or genic infection with sequestra; or may result n disease in the spine, from which the pus may el forward to find its exit on the lateral aspect even the front of the thorax. Sinuses over the num are often of specific origin.

Abdominal sinuses near the umbilicus may be due a vestigial remnant connected with the omphalo-enteric duct. The discharge in these cases is racteristically mucoid. Tubercle not infrequently es rise to a sinus at the umbilicus. Sinuses in the region or over the gall-bladder area are often ociated with appendicitis, or gall-stones, or mpletely successful interference for these condi-ns, so that either overlooked enteroliths or left-over -stones are the commonest causes, and this sibility must first be eliminated. Occasionally a growth in the bowel not otherwise suspected es rise to a sinus, but in this instance the latter n the midst of a characteristically hard area, or induration soon makes its appearance. So-called -sided appendicitis, the result of infected sacculi he sigmoid, may also cause and keep up sinuses in left iliac fossa.

Sinuses on the posterior aspect of the abdomen probably associated with retroperitoneal infections perirenal phlegmons.

In the *perineum* the urethra and the anal canal or um are always to be looked upon as the most ly situations for causative factors. Any sinus in an inch of the rectum probably owes its origin to a communication with the bowel, and a diagnosis can be made by feeling for the small indurated area, which, in these circumstances, can always be detected between the mouth of the sinus and the anus, just as if a wire had been buried in the tissues. A sinus immediately behind the anus may be of congenital origin, the result of a post-anal dermoid or some remnant of the neurenteric canal.

About the coccyx sinuses are often of obscure origin, and it may be most difficult to find the cause and to bring about their cure. The prognosis should not be too optimistic.

A sinus on the *sole of the foot* is highly suggestive of a perforating ulcer, and it may be one of the earlier signs of a central nervous lesion, and is certainly often present when the latter is suspected, but the ordinary signs are not sufficiently clear.

Actinomycosis is characteristically associated with multiple sinuses. For this condition iodine administered in fresh milk has proved wonderfully successful. The treatment begins with 7 minims of the fresh tincture in 2 ounces of milk, thrice daily, after food, but the dose may be increased to 20 minims thrice daily without fear of evil consequences.

Residual sinuses—that is to say, cases in which the cause has been found and removed and the sinus still persists or sinuses in which all efforts have failed to disclose the causative factor may have to be dealt with. In these circumstances a whole variety of methods have been tried, and all have been more or less successful at times. I would place first the treatment by attention to the general health under the best possible conditions. Locally, the injection of Beck's paste has sometimes proved successful, and now one would be disposed to try artificial sunlight. But of the greatest importance is probably rest for the part with firm bandaging, so that the walls of the track may be kept in apposition.

If these measures are not applicable or fail, then certain sinuses which are not too long and which do not pass between structures of great importance may be laid open in their entirety, so as to convert them into open wounds. In other cases, scraping with a sharp spoon may set up a reparative process; or, better than either of these methods when applicable, is the excision of the whole sinus track.

G. GREY TURNER, M.S. Durh., F.R.C.S. Eng.,
Professor of Surgery in the University of Durham;
Surgeon, Royal Infirmary, Newcastle-on-Tyne.

THE LATE DR. W. R. S. WATKINS.—The death took place on August 14th at his residence in Eccles of William Richard Spencer Watkins, M.B., F.R.C.S. Edin., in his forty-ninth year. Dr. Spencer Watkins was born in South Wales and received his medical education at Cardiff and at the extra-mural medical school and University of Edinburgh. He graduated in medicine in 1903, and in 1908 became a Fellow of the Royal College of Surgeons. For a time he was house surgeon and senior resident medical officer at King Edward VII. Hospital, Cardiff; later he settled in the Eccles and Pendleton district of Manchester, where he practised successfully for many years. During the war he was a surgeon in the 19th General Hospital at Alexandria, afterwards acting as medical officer of the 42nd Divisional Train (R.A.S.C.). He leaves a widow and four children.

DONATIONS AND BEQUESTS.—Lieut.-Colonel Alfred Tennant Miller, of Great Somerford, Chippenham, left £2500 for such hospitals or infirmaries in London as the executors may select; £2500 to charitable institutions in Great Britain for the benefit of those who served in the Great War to be chosen by the executors; £500 each to the Glasgow Royal Infirmary, the Western Infirmary, Glasgow, the Victoria Infirmary, Glasgow, the Royal Infirmary, Edinburgh, and the Malmesbury Cottage Hospital.—Mr. Warren Tay, F.R.C.S., Croydon, Surrey, left £1000 to the London Hospital Medical College, £750 to the Royal London Ophthalmic Hospital, Moorfields, E.C., and £250 to the Queen's Hospital for Children, Hackney.—Mrs. Ellen Boyd, of Twyford, Berks, besides other bequests, gave £1000 each to King Edward's Hospital Fund for London and King's College Hospital, £500 to Maidenhead Cottage Hospital, £250 to the Royal Berkshire Hospital, Reading, and £1650 to other charities.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the 1926 statistics of four county boroughs and two urban districts :—

Name of district and mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Heart disease.	Diarrhœa under 2 years.	Infant mortality.	Maternal mort. from childbirth.
Brighton .. .. (139,500)	14·0	12·5	1·08	1·86	1·3	1·9	11·0	67	4·8

Brighton.

Dr. Duncan Forbes says the outstanding feature of the year's work is the establishment of an orthopædic scheme which has been begun in a modest way. The corporation has arranged with the Royal National Orthopædic Hospital that they should allocate five beds at their Stanmore institution for the reception of Brighton cases. Payment is to be made at the rate of £2 per week per bed occupied for patients under 16 and £2 10*s.* for patients over 16. The hospital is to appoint an orthopædic surgeon to take charge of the scheme, to pay monthly visits to an out-patient orthopædic clinic in Brighton, and to recommend an orthopædic nurse, who shall be in the whole-time employment of the Brighton Corporation. Patients are being sent to the clinic from the tuberculosis dispensary and from the infant welfare and school medical departments. It is satisfactory to know, says Dr. Forbes, that there will be fewer cripples in the future and that what cripples there are will have the best treatment for the remedy of their disablement.

Although 2000 additional dwellings have been occupied since the war, there are still bad cases of overcrowding, especially distressing when a member of the family is suffering from open tuberculosis. Until these dangerous conditions are remedied the further building of new houses must continue. The first area for slum clearance has now been completed. The chief difficulty is that tenants whose average rental is 7*s.* to 8*s.* a week cannot pay the rent of the new houses which varies from 12*s.* 6*d.* to 15*s.*, and some of the families are really unfit for new houses. Under present circumstances it is difficult to arrange the necessary move round and the slum problem can only be dealt with in piece-meal fashion. To facilitate the move round the council have bought suitable houses, which after the present tenants have been moved to the new houses will be reconditioned to receive the tenants of the slum areas at a low rental. There were 13 notifications of ophthalmia neonatorum; three cases were very mild, but four were subsequently admitted to the Brighton Sanatorium; one child admitted in a hopeless condition on the tenth day of the disease lost the sight of both eyes, and another admitted on the twelfth day lost the sight of one eye. Out of the 105 milk samples examined for tubercle 13, or 12·4 per cent., gave a positive result. As a result nine cows were dealt with under the Tuberculosis Order, but in five instances no infecting cow was found, probably owing to drying off, removal, or slaughter before the farms were visited. The discover of tuberculous calves at the abattoir has led to th elimination of one or two tuberculous cows fro milk herds as the result of following up.

Hastings.

Dr. G. R. Bruce points out that the death-rate just over 15 becomes 10·8 when corrected for age an sex constitution of the population. The number new cases at the infant centres was about 77 per cen of the total number of births. The work at the tw antenatal clinics has made good progress, the atten ance at one being nearly double that of the previo year. The Fernbank Maternity Home, a voluntar institution, accommodated 100 confinement cases b could easily take 200. Forty of those admitted we municipal cases, for whom the corporation guarante the full fee of 2½ guineas. There is no waiting-list f patients with tubercle. Throughout the ye negotiations have continued with the Royal Ea Sussex Hospital for the provision of an orthopæd clinic, and it is hoped that this scheme will be progress during 1927.

Housing activities have included the completion 48 flats for the rehousing of tenants from the clearan scheme in the old town, also 50 steel houses on o estate and the commencement of 50 on anothe When these are complete the corporation will ha built nearly 500 houses since the war, but this w not, says Dr. Bruce, "solve the problem either overcrowding or of unhygienic houses, nor, unfo tunately, of the unsatisfactory tenant." The ma source of the water-supply is eight deep wells in t Ashdown Sand with a supplemental supply from t Brede River. The present supply is inadequate meet the full pressure of the summer season and t supplementary supply has to be chlorinated. Duri 1926 application was made to Parliament for power obtain water from an area in the chalk betwe Eastbourne and Brighton. The application w opposed by neighbouring authorities and thrown ou mainly on the ground that water-bearing areas near Hastings had not been exhausted. The successf solution of the water difficulty to meet present a future needs is one of the most pressing public heal problems before the corporation. During 19 88 cows were slaughtered at the knacker's establis ment within the borough under the Tuberculo Order, the majority coming from the milk-produci districts of East Sussex and Kent, and two fr dairy farms within the borough. The hours of brig sunshine registered during 1926 were 1588·5.

Carlisle.

Dr. Joseph Beard reports that 24 samples of fre cow's milk and four of pasteurised were examined tubercle bacilli. One sample from an outside da gave a positive result. The county veterina inspector examined 46 cows on the farm and fou three with disease of the udder. The city inspec had samples examined from a suspected animal each of two farms. As a result both were slaughte under the Order, and advanced disease was fou post mortem. Up to the end of the year the c poration had received the sanction of the Ministry the erection of 1344 houses—160 parlour and 11 non-parlour. Of these, 984 have been erect The sanitary inspector's report gives some p ticulars of the move round of the tenants. Thirty- new houses were built for the accommodation 38 tenants dishoused under an improvement sche Only six of the 38 elected to take the new hous and 32 had to be rehoused by the method of exchan In connexion with the demolition scheme 24 hou were erected on one of the estates, but only five of 36 tenants of the demolished houses would take new ones and the remaining 31 were accommoda by exchanges arranged through the sanitary inspect In the last case several of the tenants had alre moved once from another condemned area, and inspectors found great difficulty in getting priv owners to accept them for the second move.

Bury.

Dr. G. Granville Buckley says the worst feature in he 1926 figures is the maternal death-rate from hildbirth. Of the eight deaths, five were due to clampsia. Some of these deaths might undoubtedly e prevented, he says, if expectant mothers would ither consult their own doctor or attend at the ntenatal clinic. The antenatal clinic was attended y 52 new cases, the total births in the borough eing 816. The conversion of privies into w.c.s is roceeding very quickly; 1588 were dealt with uring 1926. The chief occupations of Bury are the anufacture of textile goods, machinery, paper, and lt hats. The sewage is of a complex nature, and ontains trade waste from tanneries, fell-mongers, ool-scouring, hatters, and breweries, and three eparate systems follow the sedimentation tanks at he sewage works—namely, 3 acres of double contact eds, 2 acres of percolating beds, and a recently nstalled unit on the activated sludge system worked n the surface aeration principle. At present the udge is disposed of by lagooning, but a complete udge pressing plant is being installed. Emissions of lack smoke which exceed the limit of two minutes per alf-hour allowed for mill chimneys are notified t once to the firm, in order that the cause may be moved promptly. This action is much appreciated y the mill-owners. Bury has had a public abattoir nce 1903. It is modern in every respect, with ilway siding and cattle dock, so that animals arriving y rail need not be driven through the streets.

Shrewsbury.

Dr. A. D. Symons claims that Shrewsbury has as mplete provision for maternity needs as any town its size. The births numbered 588, and the new ses at the antenatal clinic show a steady increase—iz., 59 in 1924, 94 in 1925, and 123 in 1926. The aternity home is conducted by the Nursing Associaon, and patients are examined at the antenatal inic before admission. Dr. Symons mentions as vidence of a "brighter Shrewsbury" movement he attention given to æsthetic considerations in chitectural development and to the repainting and reservation of the old black-and-white houses, and es on to say that the movement would receive a rther impetus if the town council would adopt ore efficient methods for the cleansing of the streets d the removal of refuse. The prosperity of the wn will be increased if cleanliness combined with ntiquity renders it more attractive to visitors. The ain streets now have a waterproof surface, he says, d should be swilled in the early morning. Sweeping the pavements opposite shops should not be rmitted after 9 A.M. Modern dust-carts with a low dy and an efficient cover should be substituted for he high carts, which create clouds of dust when a st receptacle is emptied into them. Refuse tips ed not be a nuisance, and an energetic supervisor ould be appointed to see that they are properly vered over with soil, &c. Shrewsbury is not a very noky place, but there are about a dozen works imneys which intermittently belch forth large antities of smoke, including three under the control the corporation. As the town lies low, smoke is t readily blown away, but tends to hang. The mestic smoke is being reduced by the large use of s. There are 2865 gas fires and 5623 gas cookers the 7000 houses. More houses were built last ar than in any year since the outbreak of the war—mely, 90 municipal, 76 by private enterprise with ate assistance, and 32 others. A further 101 unicipal houses will be completed during 1927.

In the selection of tenants preference is given to ose with large families. The practice of taking in dgers was one of the restrictions imposed on the nants, but a recent survey showed that lodgers ere being taken in 24 per cent. of the houses on he estate. In future application will have to be ade to the housing committee for leave to take dgers and will receive reasonable consideration. A campaign for cleaner milk was started during the year. The accepted limit for dirt in milk, says Dr. Symons, is two parts per 100,000. Proceedings were taken against a milk-seller whose milk showed 40 parts. The retailer pleaded a warranty; a summons was then issued against the wholesaler, but the magistrates dismissed the case. Another case was that of a cow-keeper who supplied milk 16 per cent. deficient in fat. An appeal to the cow confirmed the fact that the cows were giving milk thus poor in fat. The conclusion arrived at was that the cows were old, in poor condition, and badly fed, but that as there was no adulteration no legal action could be taken. Shrewsbury has a public abattoir but also two small private slaughter-houses.

Weston-super-Mare.

Dr. John Wallace mentions that two water-supply schemes are under consideration. The present supply from Banwell spring is a limestone water which is pumped to two reservoirs and to a water tower on Worlebury Hill (450 feet), which is capable of supplying the highest buildings in the district. The only streams in the district are "rhynes," by means of which land drainage is effected. The rhynes are considerably polluted by manured lands and pig and cattle sheds, and it is difficult to prevent this. Flooding causes complaints, and is relieved by the widening of culverts and the clearing of the rhynes. Gas is so universally in use for heating and cooking that the house refuse contains little ash. Also it is often difficult to see any smoke from which to judge the direction of the wind. Weston has a public abattoir and no private slaughter-houses. The hours of bright sunshine in 1926 were 1269·7, nearly 200 less than the previous ten years' average of 1454·2.

SCHOOL MEDICAL SERVICE.

—	No. on roll.	Average attendance.	Routine inspection.	Special re-inspection.	Per cent. of defects.
Blackburn .	17,065	15,009	4863*	6447	22·6
Coventry .	21,274	19,120	6428	8021	25·9
Scarborough	n.s.	n.s.	1315	1052	13·15

* With 1413 routine inspections outside the code groups, this is 6276. n.s., not stated.

Blackburn.

Dr. Oscar M. Holden describes the system of coördination by which, while each medical officer has his own duties, yet all share in the school work. Thus the medical officer of health is the school medical officer and assists with routine medical inspections as the need arises, and the assistant school medical officer who does the largest share of the school work is also assistant medical officer of health. The woman assistant medical officer devotes part of her time to school work, and the tuberculosis officer, who is also resident medical officer of the corporation hospital, is from time to time called upon to do routine school inspections. There is also close coördination in the work—for example, the record-cards of children who have attended the welfare centres are forwarded on to the school side upon the children reaching the age of 5. The children under 5 attending school remain under the care of the welfare department, and the health visitors continue to go to the homes when necessary. In school a "march-past" is made of these infants before the school medical inspector, and in this way obvious defects can be detected and treated. Then, again, the school dentist devotes 12 sessions to the maternity and child welfare department.

Dr. Holden deprecates the wholesale removal of moderately enlarged but healthy tonsils. Those whom he recommends for operative measures are the cases with enlarged, unhealthy tonsils and

adenoids, especially those who are mouth-breathers and whose past history consists of a succession of catarrhs and sore-throats. In his note on rheumatism he shows that in connexion with this disease it is imperative that a careful scrutiny be maintained on the condition of the throat and mouth in school-children. His very rational outlook has its result in the small proportion of parents who refuse to have the operations performed that have been recommended; out of 265 cases where treatment was advised 221 actually received operation under the authorities' scheme, and several others were dealt with through other channels. Special attention is given to after care of these cases at the clinic for remedial gymnastics in the form of breathing exercises and training in correct respiration, without which, Dr. Holden says, the operation of removal of adenoids is a waste of time and energy. The number of exceptional children noted is in general rather low, but accommodation seems to have been found for most of them, except that there is much need for more places in the residential open-air school. With the cripple children, however, the reverse is true. The scheme for the detection of crippling defects is certainly fairly comprehensive, including the work of an orthopædic surgeon, Dr. Briggs, and he is in close touch with the valuable clinic for remedial gymnastics; but there is no special physically defective school, which is obviously needed, and its provision could make it possible to reduce the unfortunately large number of children who have had to lose their treatment at the clinic owing to the inability of the parents to bring them.

Coventry.

Dr. E. H. Snell draws attention to the varying percentage of children who are said to require operative treatment for enlarged tonsils, and it is suggested that this depends so much on individual opinion that figures compiled by different doctors are of no comparative value. For instance, in 1914 and 1919, when an assistant school medical officer (Dr. Newton) was working alone, the percentage of cases referred for operation was 2·5 and 3 per cent. respectively; while later, when other doctors were also working, it was higher; 7 per cent. in 1925 and 16 per cent. in 1926. The ratio is reflected inversely in the proportion of those referred who were actually treated; for in 1925 this was 25 per cent., while in 1926 it was under 20 per cent.—i.e., out of five children who were recommended for treatment in only one was it actually secured. But the increase in the number of cases referred may be due not merely to personal equation but to increasing realisation of the value of removing a septic focus or pathway for infection. We note that last year Dr. Newton himself was specially investigating the subject of rheumatism, in which the value of efficient tonsillectomy is becoming widely recognised, particularly in reducing the liability to cardiac complications.

There seems to be a large number of delicate children in Coventry, and it is a sign of the sound sense of the city that the residential camp at Corley is being rebuilt, with accommodation for 90 instead of 30 children. Another indication of the wisdom of this authority is given by the fact that the school for mentally deficient children, which is doing excellent work, was established as far back as 1910.

The report of the school dentists alludes to the harm done to the teeth by soft food and fermenting carbohydrates which adhere to the teeth and gums. As to the causation of dental caries, there are several different schools of thought, one regarding as the essential cause the lack of vitamin D in the diet, and another blaming especially oral sepsis, and advocating mouth-washes, toothbrush drill, and the like. A third is that cited here, in favour of which there was striking evidence in the Birmingham report for 1925, where there is a comparison of the conditions of the teeth of the children in Birmingham with those in New Zealand. Those in the Dominion were immensely worse, although the standards of diet and of general hygiene are much better, th determining factor being apparently the larger amoun of sweets and biscuits eaten there, causing th carbohydrate fermentation alluded to by the Coventr dentists, Messrs. Raeside and Shelvin, who would however, of course, agree that the right idea c prophylaxis against dental caries is to use ever method and to interpret the terms correct diet an oral hygiene in the broadest possible sense.

Scarborough.

Dr. S. F. Linton describes the coördination c school and general public health work appropriat for a small area such as Scarborough. Child welfar work is carried out on the premises of the schoo clinic by the assistant school medical officer, D Annie Roxburgh. Debilitated children under schoo age continue under the care of the centre and th health visitors until they come to school, when the are transferred to the school medical service. A records are kept of all cases continuity of work maintained. It is much to be regretted that in the interest of "economy" the nursery school ha been closed.

There seems to have been a great improvemen in the cleanliness of the school-children of the boroug but ringworm causes much trouble and loss of scho attendance. Dr. Linton, for example, cites the case of child who has been kept out of school for two yea He wonders whether it would not be justifiable allow such children to remain at school provid that they wear linen caps. Other authorities ha found that infection is limited if under such a c the scalp is covered with a thick greasy ointmen but a far better method is the use of X rays, whi reduce the period of exclusion to two or three weel There are no special schools in Scarborough. The is less need for an open-air school in Scarborou Dr. Linton thinks, than in a dense industrial cent A special class is provided for the dull and backwa including many feeble-minded children, and t opening of the Orthopædic Hospital at Kirbymoorsi has marked an advance in the treatment of crippl for it affords institutional and specialist treatme Apart from this, Dr. Crockatt, the orthopædic surge holds a monthly clinic at the local hospital, where masseuse attends and gives instruction to parents.

MENTAL HOSPITAL REPORTS.

THE *Cumberland and Westmorland Mental Hosp* had 815 patients resident at the end of the ye There has been a marked diminution in the m admission since the war, and those sent in are nea all incurable. The superintendent feels that this m reflect an unwillingness to certify in early sta and regrets the necessity of having to refuse admiss to those who are willing to enter the hospital with certification. The recovery-rate was 32·7 per ce and the death-rate 6·7 per cent. The general hea was good, except for influenza. Parole on the est is allowed to 20 men but to none outside, and th are no open wards.

The *Glamorgan County Mental Hospital* at Bridg reports an increase of 73 in its population, chi males. This is ascribed mainly to the lowered dea rate—8·6 per cent.—and the smaller number relieved patients discharged. The number of patients—1076—is a record and means overcrowd The recovery-rate was 22·8 per cent. The numbe deaths from tuberculosis has fallen from 31 to Eighty post-mortem examinations were held. general health was good and free from zymotic dise apart from 84 cases of influenza. A dentist has b appointed to attend weekly. Parole is allowed bey the estate to 9 men and to 85 more within the grou but to no women, and there are no open doors ex in the convalescent villa. There is a small laborat and the visiting commissioners urge the appo ment of a technical assistant, so that full use ma made of it. General paralytics have not been tre

malaria as yet. Fourteen attendants and two nurses obtained their certificate in May.

The *City of Leicester Mental Hospital* at West Humberstone had 923 patients on its books on Dec. 31st, an increase of 33 during the year. So many reports speak of the urgent need for increased accommodation that it is interesting to find Dr. J. F. Dixon pleading, not for more beds in mental hospitals, but for decertification of a large proportion of their population, which might well be housed in special institutions for harmless and helpless dements. The ratio of Leicester "insane" to the city population is now 1 in 304; five years ago it was 1 in 355. The recovery-rate for the year was 44·2 per cent. and the death-rate 5·5 per cent. The cause of death was verified by autopsy in 82 per cent. of the cases. The general health in 1926 was good, except for some influenza. There were no cases of zymotic disease. Forty-eight per cent. of men patients and 37 per cent. of the women were on full or limited parole, and leave of absence was granted 1491 times to men and 1013 times to women. Seventy-seven per cent. of the patients were kept fully employed. Small parties of female patients went to the cinemas regularly and others for motor drives into the country. The farm and garden again yielded a substantial profit. A new laboratory assistant has been appointed and the pathological work has therefore been extended. Malarial inoculation therapy was tried for general paralytics; 3 out of 13 were discharged "recovered." Since 1924, when this treatment was first used, 7 per cent. of the cases treated have been discharged well, 15 per cent. improved mentally and physically, while 31 per cent. remain unimproved. An investigation into the incidence of syphilis in the chronic population of the hospital has been commenced. So far 15 per cent. of the men examined (201) have shown a positive Wassermann reaction. In the summer tinea marginata cruris was again troublesome on the male side. The visiting dentist supplies a report stating that he has treated 287 patients and inspected and passed 44 more. He remarks on the keenness of the nursing staff in carrying out the intensive course of dental hygiene which is of such importance in cleaning up a septic mouth. A complete set is given of all nurses and attendants who have obtained their M.P.A. certificate. The cricket team had a successful season.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 6TH, 1927.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 2 (last week 185); scarlet fever, 1234; diphtheria, 71; enteric fever, 73; pneumonia, 489; puerperal fever, 38; puerperal pyrexia, 73; cerebro-spinal fever, 9; acute poliomyelitis, 14; acute polioencephalitis, 1; encephalitis lethargica, 21; dysentery, 7; ophthalmia neonatorum, 104. There was 1 case of cholera, plague, or typhus fever notified during the week.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 3 (1) from enteric fever, 31 (1) from measles, 2 (0) from scarlet fever, 13 (3) from whooping-cough, 24 (5) from diphtheria, 45 (7) from diarrhœa and enteritis under two years, and 16 (6) from influenza. The figures in parentheses are those for London itself.

The number of stillbirths registered during the week was 241 in the great towns, including 42 in London.

REMUNERATION OF CORONERS.—The coroners of Cheshire districts have sent in an application to the county authorities for increased remuneration owing to additional work caused by the provisions of the Coroners Amendment Act, 1926, and the requirements of the Home Office.

Special Articles.

COMPULSORY TREATMENT OF VENEREAL DISEASE.

THE NEW SOUTH WALES PLAN.

THE report of the Director-General of Public Health in New South Wales for the year 1925 contains paragraphs on the working of the system of compulsory notification of venereal disease under the Venereal Disease Act of 1918 (No. 46 of the New South Wales Acts of 1918). Notification is by number, not by name; if, however, a patient fails to continue under treatment till cured the medical attendant is required to report the name and address to the Commissioner, who is a medical practitioner nominated for the purposes of the Act by the Governor of New South Wales. The patient is then informed of the penalties to which he is liable unless he resumes treatment. In practically all cases where a patient can be reached resumption of treatment follows; in only a few instances, observes the report, has it been found necessary to resort to prosecution. The grave difficulty of this process of following up defaulters—a difficulty mentioned also in the recent report of the Scottish Board of Health—is due to the large percentage of persons who give the doctor a false name or wrong address. In 1925 it was necessary to notify 955 persons in New South Wales for failure to continue treatment; of these no fewer than 538 (about 55 per cent.) could not be traced owing to a wrong name or false address; 241 resumed treatment; and 176 cases were under investigation at the end of the year.

In England we still seem to be far from compulsory notification of venereal disease, and, except in local examples such as the Bradford Corporation Act of 1925, there is an evident reluctance to make it a criminal offence to fail to notify or to omit to undergo treatment. It is nevertheless interesting to study the features of a far-reaching enactment like the Venereal Diseases Act of New South Wales. Power was given to the Governor to bring the Act into force in different areas and at different times; it is now in force everywhere in New South Wales. In forbidding the advertisement of remedies, and in insisting that treatment of venereal disease shall be by medical practitioners only, the Act corresponds with our own Venereal Disease Act of 1917. But in many ways it goes much further. Under Section 4 a person suffering from this form of disease must, within three days of becoming aware of his condition, consult a medical practitioner, to whom he must furnish his correct name, occupation, and address, and to whom he must submit himself for treatment. Disobedience of this section is punishable with a fine of £100 or imprisonment for three months. The section includes a special provision for professional secrecy in the following terms: "Any medical practitioner who, otherwise than in accordance with the provisions of this Act, communicates to any person or in any other way makes known any name or address so furnished to him shall be liable to a penalty not exceeding £100 and shall be deemed to be guilty of professionally infamous conduct." Under Section 9 the medical practitioner must notify the Commissioner on a prescribed form within a prescribed period; failure to do so involves a fine not exceeding £20 on the first occasion and not less than £20 or more than £100 on any subsequent occasion. Marriage by a venereal disease patient while knowingly in an infectious stage is an indictable offence punishable with the substantial penalty of £500 fine or five years' hard labour or both. In this connexion strict ideas of professional secrecy are disturbed in a manner which anticipates a passage in Lord Riddell's recent address. If the doctor has reason to believe that a

person suffering from venereal disease intends to contract a marriage, he may (after notifying the patient of his intention) inform the person whom he has reason to believe to be the other party, or he may inform the parent or guardian or the Commissioner. Such communication is absolutely privileged. In addition to this protection (which is contained in Section 12), Section 19 enacts that all proceedings under the Act are to be privileged, and Section 20 forbids the publication of reports of any such proceedings unless with the written authority of the Commissioner. Medical practitioners can give certificates of cure or freedom from disease; and here it would appear that some kind of protection for the certifying doctor was deemed necessary. Section 18 states that "No certificate, notice, or other communication, verbal or in writing, given by a medical practitioner for the purposes of this Act, bona fide and without negligence, that any person is suffering from venereal disease shall be made the ground of any legal proceedings civil or criminal." Practitioners in England, with recent experience of the heavy personal liability involved in certification under the Lunacy Acts, will notice the language of the New South Wales Act; this kind of protection may be somewhat illusory, since it is always possible to get a claim placed before a jury by imputing bad faith or negligence.

Other features of this very comprehensive Act may be mentioned briefly. As already indicated, patients must remain under treatment till they have received a certificate that they are cured or free from their disease. They must notify any change of address, and there is provision for change of medical attendant. Treatment must continue till cure is effected notwithstanding the fact that the patient has ceased to be liable to convey infection. The patient's name and address must be reported on failure to continue treatment. Patients (or, in the case of children, their parents or guardians) are to receive special medical warning of the nature of their disease and of the dangers of contagion. It is made an offence to work in a shop, factory, hotel, restaurant, &c., when suffering from venereal disease. To infect anyone knowingly is punishable with £100 fine or 12 months' imprisonment or both. Brothel-keepers commit an offence if they knowingly allow the presence of a female patient, and certificates of cure or freedom from disease are not to be used in relation to prostitution. Departmental regulations can be made for various purposes such as the treatment and examination of patients and the supply of drugs. While the New South Wales Act is by no means unique, it is a useful type for those who would like to frame a common measure for adoption by international convention. In this respect the record of its actual working is particularly valuable. Should such legislation become universal, the old professional ideals of secrecy would become impossible; but the doctor's duty or power to disclose confidential information is naturally a very different matter when a new range of criminal offences is introduced in relation to treatment for venereal disease. Such new legislation would extend the occasions on which a doctor, like any other citizen, may feel obliged to warn the proper authorities that a crime has been, or is about to be, committed. Nevertheless, it would seem desirable that a patient should be able to obtain and rely upon a specific assurance that, so long as he followed the prescribed treatment, secrecy would be absolute; at the same time he should be specifically warned that if he failed to continue his treatment, or if he did not do his best to facilitate his cure, the privilege of secrecy might be withdrawn.

LONDON FEVER HOSPITAL.—The total income of this hospital last year was £22,911, over £1600 less than last; and to meet the deficit the committee has had to increase the overdraft at the bank, which now amounts to £4600. There is an urgent need for reconstructing the old isolation block, but £10,000 would be required for this purpose. Patients' fees last year amounted to £14,748.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

The Mississippi Floods.

THE gigantic task of relieving the victims of the floods in the Mississippi Valley has now virtually ended and the American Red Cross has been able to close its local headquarters at New Orleans. More than half a million people have been helped by the Red Cross and coöperating agencies and subscriptions to the Relief Fund have amounted to over 16 million dollars. As the floods subsided, and the population was able to return, their health was with difficulty maintained. Inoculation against typhoid was done on a large scale, sewage disposal was regulated, water supplies were purified, dead animals were buried with the help of seven tons of dynamite, and an active antimosquito campaign was started, in the course of which 2480 barrels of oil and 210,750 yards of mosquito netting were used. No serious outbreak of disease has been reported; indeed, it is said that morbidity this year has been below normal. The Red Cross has furnished returning refugees with two weeks' rations, live stock and poultry, and necessary household equipment, and has impressed on them the need for observing elementary principles of hygiene.

Typhoid Fever in Montreal.

For some time sanitarians in the United States have been aware that there was an epidemic of typhoid fever in Montreal, but in spite of repeated efforts it appeared to be impossible to get a full statement of the facts. Recently, however, with the permission of the Deputy Minister of Health of Canada, the Surgeon-General of the U.S. Public Health Service appointed a board of investigation. Their survey occupied the last half of the month of June and they have now reported. Apparently the Montreal epidemic began in February and went on intermittently until well into the summer. Between March 1st and June 28th there were 4755 cases of typhoid with 453 deaths. The board consider that it was due to infection of milk delivered by the Montreal Dairy Company. "The preponderance of evidence," they add, "is that a very considerable proportion of the infected milk was passed through and distributed from the plant without being subjected to pasteurisation treatment. The medical officer of health seems to have had his hands tied through lack of personnel, and although there are over 40 pasteurisation plants in the city there is only one person engaged to inspect them and he has had other duties besides. On the question of responsibility the board report as follows:—

"Our definite impression is that the city health officer of Montreal has honestly and sincerely recognised his responsibilities during the epidemic and has done his best to render efficient service under most difficult and trying circumstances. It is evident that he should be given ample authority and adequate efficient personnel at once to cope effectively with the present typhoid situation and with other serious preventable disease situations which are likely under existing conditions to develop in Montreal in the future . . . . Since the epidemic began the city health forces have been augmented by the temporary detail of two sanitary engineers and one sanitary inspector from the provincial health department. This provincial force took charge of the milk plant and the creamery of the Montreal Dairy Co. Ltd., on May 21st and apparently has managed them since in a highly efficient manner."

The board go on to suggest that steps be taken to bring about "radical improvement in sanitary conditions under which milk and milk products are produced, handled, or processed in the city of Montreal or in any other place in the Province of Quebec within a radius of 100 miles of the city of Montreal for export to the United States," and recommend that "such milk or milk products after reaching points to which shipped in this country and before being distributed to consumers be pasteurised or otherwise processed under official supervision so as to be rendered free from typhoid, tuberculosis, or any other infectious

:ely to endanger human health." As a result of e report the use of Montreal milk and cream on ning cars bound for the United States has been rbidden. New York City has placed an embargo i milk from Montreal and its vicinity, while the ew York State Department has issued a warning that ontreal is not a comparatively safe resort for summer sitors.

The Drift to Big Towns.

A recent study by the Connecticut State Depart-ent of Health shows that 80 per cent. of towns with population of less than 1000 are without medical actitioners, and in about one-third of the towns in e State there is no resident doctor. The problem not confined to one State and has been receiving tention for some time. One solution which is often oposed is the establishment of health centres, with cilities for the practice of modern medical methods the less densely populated areas.

RED CROSS WORK IN 1926.
REPORT OF THE JOINT COUNCIL.

THE seventh report of the Joint Council of the rder of St. John of Jerusalem and the British Red oss Society, which has just been issued, covers e period from April 1st, 1926, to March 31st, 1927, id may be obtained from the offices of the Council ; 19, Berkeley-street, London, W. 1. The work of ie Council is distributed among committees specially t up to deal with medical services, auxiliary hospitals, nergency help, home service ambulance, tuberculosis, id hospital libraries. Report on the voluntary ospitals in Great Britain is reserved for separate iblication in October. The present report, which overs the other branches of the Joint Council's work, cords a gratifying revival of enthusiam for all its anches in most of the counties throughout the nited Kingdom.

Auxiliary Hospitals.

The main work of this department consists in elping officers suffering from tuberculosis, making ood the hospital stoppages during sanatorium eatment, and giving additional help in institutions here the grant paid by the Ministry of Pensions does ot cover the fees. Assistance is also rendered in cases here the Ministry of Pensions considers treatment dvisable but not absolutely essential. Applicants re finding it increasingly difficult to satisfy tribunals iat their disability is due to war service, and the ouncil comes to the aid of cases in which immediate eatment is essential pending investigation of claims. ast year 44 officers were sent to winter abroad, 3 at Montana (Palace Hotel), 8 at San Remo (Sunny-ank), 5 at Arosa (Sanatorium Altein), and individuals lsewhere. The Hospital for Officers at Brighton as now only 25 beds, mostly occupied by medical ases, a large proportion of them being duodenal lcer. The average age of the 85 patients admitted o this hospital during the year was 45 years.

Home Ambulance Service.

This service is solving one of the country doctor's reatest difficulties by bringing serious cases of accident r disease rapidly to the spot where they can be ost efficiently treated. Although ambulances to the alue of more than £100,000 have been provided by he Joint Council, the responsibility for running, ousing, and maintaining them and for raising funds s undertaken by voluntary workers, many of whom ffer to tend the patients during the journey, whether y day or night. Arrangement is now being made or ambulances to work with the lifeboats, cars tanding by ready to complete the work which life-oats have begun. Another recent development is he mitigation of road accidents. Last year, it is ecalled, 138,774 persons were killed or injured by ehicles on the highways, and the Ambulance Com-nittee has accepted the task of coöperating with the olice and the automobile associations in organising an efficient road service. The aim is to secure that one or more persons able and willing to give first-aid, and possessed of the necessary training and equip-ment, shall be within easy reach of the scene, wherever an accident happens, on any of the more frequented roads of the country. This will mean training sections in the smaller towns and villages to be linked up with the larger units. At some points first-aid boxes with bandages and dressings will be provided on busy roads, week-end patrols with splints and other equipment and, if necessary, tent or other shelter for injured persons at a convenient point. The total number of ambulance stations in the country equipped by the Committee is 326, not counting 50 ambulances affiliated to the service. A certain number have been released during the year by the municipalisation of the ambulance service in some of the larger towns.

Mobile X Ray Service.

This is a unit comprising a 16-inch induction coil outfit with mercury interrupter and rectifier run by an 8 kilowatt direct current dynamo off the 35 h.p. Fiat car engine and developing 125 volts with a maximum output of 70 ampères. The unit makes it possible to take any kind of X ray photograph of patients confined to bed. There is also a full-size radiographic couch available for work in the smaller hospitals in and around London. All the reports are made by a member of the Institute of Radiology.

Tuberculosis.

A grant of £2950 was made by the Tuberculosis Committee to the Factory in the Field, Leeds, where of the 92 men employed 62 are ex-Service pensioned tuberculous men. A grant of £3500 was also made to the Central Fund for the Welfare of Tuberculous Persons to establish a firewood factory in London to employ tuberculous pensioners ; owing to unforeseen difficulties the factory has not so far paid its way. Scio House, Putney, continues to meet the need of a home for ex-officer tuberculous patients.

The Services.

ROYAL NAVAL VOLUNTEER RESERVE.

D. A. Imrie, late Temp. Surg., R.N., to be Surg.-Lt.
Surg.-Lt. F. E. Stabler to be Surg.

ROYAL ARMY MEDICAL CORPS.

Capt. H. R. L'Estrange, half-pay list, late R.A.M.C., on completion of a period of five years on the half-pay list, retires on retired pay on account of ill-health and is granted the rank of Maj.

Capts. F. A. L'Estrange (Prov.), W. G. D. McCall (Prov.), J. M. Macfie, and H. N. Stafford to be Majs.

To be Lts. on prob. : J. M. Quinlan, L. R. S. MacFarlane, M. F. N. Griffin, J. J. O'Dwyer, W. F. Lane, Temp. Lt. de Lisle Carey (and relinquishes the temp. rank of Lt.), Temp. Lt. H. A. Ferguson (and relinquishes the temp. rank of Lt.), J. H. Anderson, M. G. de L'Isle Sturm, and D. B. O'Sullivan-Beare.

Lts. J. M. Quinlan, L. R. S. MacFarlane, and J. H. Anderson are seconded.

Lt.-Col. H. W. Symons resigns his commn. and is granted the rank of Maj.

Capt. J. Cohen, from Hygiene Cos., to be Capt.

ARMY RESERVE OF OFFICERS.

Lt. C. W. Simpson, from R.A., Reg. Army Res. of Off., to be Lt.

ROYAL AIR FORCE.

C. Sempill de Segundo (Maj., R.A.M.C. (T.F.) (retd.)), is granted a temporary commission as Flight Lt.

The undermentioned officers are granted temporary commissions as Flying Officers on attachment to the Royal Air Force : Temp. Lt. A. P. McClare, Gen. List, Army (Dental Surgeon), and Temp. Lt. S. McC. Craig, Gen. List, Army (Dental Surgeon).

The undermentioned relinquish their temporary Royal Air Force commissions on return to Army duty : Flight Lts. A. Rhodes and N. F. Smith (Capts., Army Dental Corps).

INDIAN MEDICAL SERVICE.

Lt.-Col. E. E. Waters retires.

"Audi alteram partem."

THE TOXÆMIA OF ACUTE INTESTINAL OBSTRUCTION.

To the Editor of THE LANCET.

SIR,—One of the most striking points brought out by Mr. Brockman's lecture, which you published last week, is the close relationship of this toxæmia with persistent vomiting. When vomiting is marked, whether in the experimental animal or in the human subject, the "toxæmia" is marked; when vomiting is not marked or is absent toxæmia is less evident or is absent. In a dog a (duodenal) "loop was entirely cut off from the rest of the gut whilst the blood and nerve-supply remained intact"; the continuity of the gut was assured; the animal "suffered no acute symptoms, neither did it vomit." In my view it suffered no acute symptoms, *because* it did not vomit. In the human subject the same relationship holds. Mr. Brockman cites the case of a man from whom he removed a gangrenous appendix. In the early hours of the fourth morning the patient was so ill that death appeared imminent; as the result of treatment (injection per rectum of human bile and morphia) the vomiting stopped and the patient improved. On the tenth day acute obstruction was diagnosed and a complete obstruction was found, though just before the operation the patient was smoking a cigarette, had a pulse of 70, and a soft abdomen. He felt so well as to be surprised at the request for a further operation, and apparently only hesitatingly gave consent. Are we to suppose that this man was not suffering from a toxæmia? If so, we must believe that acute intestinal obstruction per se causes no toxæmia.

I suppose every medical man of any experience has missed cases of intestinal obstruction because the signs were absent, especially the sign of persistent vomiting. Here is one:—

A few weeks ago I opened the abdomen of a young man whose state was undiagnosed. He had been "seedy" for four or five days before being sent into hospital; he had had a previous attack of colicky pains some three or four months before. When I saw him he was lying in bed looking pretty well, with a quiet pulse, no fever, moist tongue. The abdomen was generally and slightly distended. He had vomited but once or twice and was constipated. Complete obstruction by a Meckel's diverticulum was found. The lower ileum naturally was implicated. The gut immediately above the obstruction was enormously distended; it was as big as a man's forearm, was dark purple in colour; the peritoneum over it was fissured. It reminded me of the state of the uterus in cases of concealed accidental hæmorrhage. The patient died.

Here is another example, slightly different:—

A woman was admitted as a case of appendicitis with intestinal obstruction. A mass was present on the right side of the abdomen; the patient was very ill. Vomiting had been little marked. Eight or 12 inches of the lower ileum were black in colour, turgid in consistence, and stinking. At the base was a band which was the appendix; this long before had been inflamed and its tip become adherent to the base of the mesentery, a loop being formed through which a coil of gut had passed. The appendix and the gangrenous gut were excised; the cæcum was closed and the lower end of healthy ileum brought out on to the abdomen. Death on the table was expected, but according to the anæsthetist distinct improvement occurred with excision of the affected gut; the patient recovered and the wound healed by first intention. She awaits a second operation.

Clearly, in both of these cases obstruction had existed probably several days before the patients had been sent into hospital. In each the condition was undiagnosed or only recognised late, mainly because vomiting had not been marked, and with this the general condition of the patient had remained so good. Delay in the onset of persistent vomiting is a common feature of low obstruction; when obstruction is high—as when a duodenal loop is formed experimentally—vomiting occurs earlier, and th case is correspondingly more serious.

The use of bile as a rectal injection in cases o ileus has been urged before. Its modus operand as Mr. Brockman states, requires working out. Th majority who use it seem to think it influence peristalsis, opening the bowels with passage of flatu Whether it acts in this way; or, as Mr. Brockma seems to suggest, by affecting in some peculia manner the mucosa in higher reaches of the gu after absorption; or whether the results obtaine with it are merely coincidents, as your leading artic supposes possible, further inquiry may show. Th point to be stressed is this:

"In most cases after the first rectal injection of human bi the vomiting stops forthwith, and even if this is not th result at once it is very much diminished and an increas in the bile given will secure the desired result." (Brockmar

That persistent vomiting can thoroughly upse people, and create a feeling and appearance of desperat illness, even in the absence of any intestinal disorde is sufficiently evident. Thus, death from persisten sea-sickness—from the vomiting alone—has occurre A comparable condition occasionally is seen in pre nancy; persistent vomiting in mid-pregnancy creat all the appearances of a grave toxæmia. That th vomiting is the cause of the toxæmia, not that toxæmia precedes and causes the vomiting, wa thrashed out in your correspondence columns in 192 Stop the vomiting and you cure the patient. It is th same in intestinal obstruction.

But just as obstetricians (yet not all) impute th pernicious vomiting of pregnancy to a precedin toxæmia, so surgeons, basing their opinion on exper mental work, impute the toxæmia of acute intestin obstruction to absorption of poisons from the conten of the obstructed gut. But the evidence for this vie is not beyond criticism—as in some part I hav shown. Here is a further criticism. It has bee argued that the pressure within the obstructed gu rises enormously, and that this favours absorptio But it is plain, if the pressure within the obstructe gut does rise to any great extent, and remains raise that the capillaries in the intestinal wall will b correspondingly compressed and even occluded, an that the circulation through this part will be material diminished or even stopped. That such occurs common knowledge; it explains the changes in th gut and the growth of bacteria within the lume How then can poison from the contents of such a co be absorbed? It is manifest that this argument invalid. The evidence is that when the gut becom obstructed fluid is poured into the lumen of th obstructed part, causing the distension of the gut an affording the material for the copious vomiting, an ultimately the dehydration of the patient. Apa from hepatic activity, by which nocuous bodi absorbed by the gut are rendered innocuous to th systemic blood—though the liver seems unable destroy the products of intestinal gangrene—the is reason to think the poisons within the lume formed in intestinal obstruction are not absorbe —that indeed, according to the site of the obstructio they are to a large extent voided.

I am, Sir, yours faithfully,

R. H. PARAMORE, F.R.C.S. Eng.

Rugby, August 13th, 1927.

SINGER'S ORAL METHOD OF LIPIODOL INJECTION.

To the Editor of THE LANCET.

SIR,—The above method is so satisfactory that brief description of it may be of interest to tho by whom it has not yet been tried. If the patient full coöperation can be obtained it involves litt discomfort. On a recent visit to this country, Dr. J. Singer, of St. Louis, kindly came to the City of Londo Hospital for Diseases of the Heart and Lung Victoria Park, E., and demonstrated his method. W were impressed by its ease and simplicity, as well

he radiograms obtained. We have since tried method with very satisfactory results.
ie patient sits on a chair and leans towards the to be injected, the head supported by his hand. c.cm. syringe is filled with well-warmed lipiodol. he syringe is attached a smooth-ended cannula, h 10 cm., bore 3 mm. The tongue is protruded ir as possible. This is held as in laryngoscopy. end of the cannula is placed over the base of tongue between the uvula and the side of the ynx. No part of the mouth must be touched. oil is now injected slowly while the patient is uraged to breathe deeply. No local anæsthetic sed, the only preparation needed is the usual for iodine idiosyncrasy, and of course to empty, osture, as far as possible the cavities in cases ronchiectasis. Should the patient be found erant it is an easy matter to revert to the thyroid method. In one recent case, for example, irst drops of oil induced a violent paroxysm of hing and the expectoration of large quantities of Therefore the oral method was abandoned and cricothyroid membrane method, with the usual tion of cocaine, used and no difficulty was rienced. The essentials of the oral method appear the full protrusion of the tongue producing closure ie œsophagus and deep inspirations throughout whole proceeding.
e method is not suitable for young children or e a picture of the apex is desired.

We are, Sir, yours faithfully,

F. G. CHANDLER,
Physician;
W. BURTON WOOD,
Assistant Physician, City of London Chest
gust 9th, 1927. Hospital, Victoria Park, E.

D CELLS AND HÆMOGLOBIN NORMALS.

To the Editor of THE LANCET.

R,—I have read with interest the annotation his subject in your issue of August 13th. The tions raised therein have to do with what may alled the physics of the blood. In this depart- of investigation the blood is to be regarded mixture of two constituents only, serum and oglobin, in varying proportions, and no con- ons can pretend to accuracy which do not take consideration in every equation the specific ties of the blood, of the serum, and of the oglobin. Given these data, which can be easily accurately determined, and an adequate alge- al technique, a number of indisputable con- ons can be established and incorporated in a l table. A definition of "standard aqueous oglobin" would be required, and a convention ld be arrived at as to the number of the red that should be contained in one cubic millimetre althy blood. The number 5,000,000 is a very enient one for purposes of calculation and for reason, if for no other, should claim precedence. the aid of this table any of the questions your le suggests can be easily answered as well as s of perhaps greater interest and importance.

I am, Sir, yours faithfully,

ton, Lancs, August 14th, 1927. B. DERHAM.

ALPATION IN EXAMINATION OF THE APPENDIX.

To the Editor of THE LANCET.

R,—Mr. J. W. Dowden, while discussing chronic ndicitis at the Section of Surgery of the B.M.A. al meeting (THE LANCET, August 13th, p. 333), ed to the necessity for judicious palpation in to ascertain the site of the main tenderness. any cases it is of the greatest use to employ two s, one of the two being the patient's right hand. right hand of the examiner having been used ly to touch over and around the suspected area aced upon it, and the patient is instructed to press on the examiner's fingers with the right hand; instruction is given that if tenderness results the patient is causing it. Invariably a free and full palpation of the appendix results whether tenderness be elicited or not; the appendix may be grievously affected without the slightest tenderness, and in this contingency it is all the more completely palpated, especially if affected. Adjuvant to this method, and in order to make assurance doubly sure, deep palpation while the patient elevates the whole of the extended right lower limb, with the right knee rigid, can be readily practised. I have frequently found the successive use of the two methods to clear the issue and to enable a correct diagnosis to be made in cases deemed doubtful or difficult to diagnose.

I am, Sir, yours faithfully,

R. CUNNINGHAM AFFLECK.
Royal Medical Society, Edinburgh, August 12th, 1927.

ASTHMA AND ARTHRITIS IN ALTERNATION.

To the Editor of THE LANCET.

SIR,—Dr. Wigoder's report in your issue of August 13th of a case of alternating asthma and rheumatoid arthritis, leads me to give a brief account of a similar case under my care at present.

Miss N., aged 70 years, first developed asthma in 1918. The following year the asthma having been controlled by vaccine treatment, she developed acute infective arthritis, the metacarpo-phalangeal and knee-joints being those chiefly affected. During the onset of the arthritis the asthma completely cleared up. The arthritis was treated with rheumatism phylacogen (P. D. and Co.) and after a prolonged course involving large doses the pyrexia disappeared and all active trouble in the joints subsided. A short while after this, in 1921, the asthma again returned, and the two conditions have relapsed, although mildly, alternately ever since. I am now on the track of an intestinal organism, a non-lactose-fermenting bacillus, which I hope is the cause in some way of both conditions, and that a further course of autogenous vaccine from this source will arrest both conditions.

As your correspondent mentions the rarity of this condition I thought an account of this case would be of interest.—I am, Sir, yours faithfully,

HAROLD O. LONG.
Stormont-road, Highgate, N., August 13th, 1927.

OTITIS MEDIA FOLLOWING NASAL SYRINGING.

To the Editor of THE LANCET.

SIR,—I have recently met with two cases of acute otitis media which resulted from the using of a syringe for douching the nose.

A. B., a girl of 18 years. After an operation on the nose for right-sided ethmoiditis she was recommended to use a syringe for cleaning out her nose. Two weeks later she attended with a subacute otitis media on the right side. This subsided, fortunately without an operation, on altering the nasal treatment and discontinuing the use of the syringe for the nose.

C. D., a man of 20 years. He had been suffering for some months with ethmoiditis on both sides and this had become much worse lately. Under treatment his condition was improving until, unfortunately, he was told to use a syringe for his nose. When he was next seen about a week later he had acute suppurative otitis media in both ears, with the usual severe symptoms. His tympanic membranes were incised and the ear condition went no further. He was advised to use the syringe no more, and to sniff the lotion up his nose instead. He had no further ear trouble.

Cases such as these are of frequent occurrence. With an ordinary simple catarrhal condition of the nose, methods other than sniffing the lotion up the nose often lead to middle-ear infection, either acute or chronic. Sniffing up a nasal douche creates a negative pressure in the nose and postnasal space, so that any infected material tends to be aspirated from the region of the Eustachian tubes. In

syringing, on the other hand, fluid is forced into the nasal recesses, and the Eustachian tubes are facing in the direct line of fire. Also, with a glass boat the head is tilted back and fluid is swept over the Eustachian openings.

I am, Sir, yours faithfully,

C. HAMBLEN THOMAS, F.R.C.S. Eng.

Harley-street, W., August 9th, 1927.

Obituary.

HENRY HARVEY LITTLEJOHN, M.B., B.Sc., F.R.C.S., F.R.S. Ed.,

REGIUS PROFESSOR OF FORENSIC MEDICINE, UNIVERSITY OF EDINBURGH.

WE regret to announce the death of Prof. Harvey Littlejohn, Professor of Forensic Medicine in the University of Edinburgh, which occurred on Tuesday last in a nursing-home in Edinburgh. He had been in delicate health for some time.

Henry Harvey Littlejohn was the only son of Sir Henry Duncan Littlejohn, who preceded his son as Professor of Forensic Medicine in the University of Edinburgh, and who was President of the Royal College of Surgeons of Edinburgh and medical officer of health for the city. Harvey Littlejohn was born in 1862 and received his medical education at Edinburgh University, where he graduated in medicine in 1886, taking later the B.Sc. and the F.R.C.S. Edin. After qualification he studied in Vienna and Berlin, and early manifested an intention to follow in his father's footsteps, for after holding posts at the Fountain Bridge Dispensary and the Royal Maternity Hospital at Edinburgh, where he worked under Sir Halliday Croom, he became medical officer of health for Sheffield. He held this post for six years, and returned to Edinburgh in 1897 to take up his appointment as Lecturer on Medical Jurisprudence and Public Health in the Edinburgh School of Medicine. He came to this post with considerable experience of its requirements, as, before proceeding to Sheffield, he had assisted his father in his departments along many lines of analogous work. In 1906 he was appointed Professor of Forensic Medicine upon his father's retirement, and he occupied the chair until his death.

During 21 years of administrative work Harvey Littlejohn gained a high reputation as a wise and tactful administrator and a learned medical jurist. His outlook on forensic medicine generally can be gathered by reading his book on the subject, which is not an ordinary text-book, but rather a well-catalogued medico-legal museum, containing admirable illustrations of post-mortem conditions in the circumstances attendant upon murderous attacks, serious accidents, and infanticide. The full descriptions attached to the pictures has made the book of great value to students and also to practitioners when called upon to study the medico-legal aspect of cases occurring in practice. His analytical method of approaching difficult subjects was well illustrated in all his writings. In a paper which he read before the Medico-Legal Society some three years ago on the subject of judicial hanging, he explained what the actual lesion to be arrived at is, how the "drop" is adjusted towards this end, and with whom the responsibility rests for the length of the "drop" and the situation of the knot; and he excelled in making similar controversial subjects clear, as he showed frequently when giving expert evidence in criminal cases. Other written works displaying the same power of imparting sound teaching and information in a simple way are a report on "Ten Years' Notification of Infectious Diseases in Edinburgh," an essay on "The Causes and Prevention of Smoke," and the health reports dealing with the city of Sheffield over the period of his office there.

At the International Medical Congress, held in London in 1913, Littlejohn was President of the Section of Forensic Medicine, a recognition of status which was well merited. At the time of death he was President of the Medico-Legal Soci and the representative of Edinburgh University the General Medical Council. In all his public w he impressed his colleagues with his capacity a judgment, while his fascinating personality had gai for him a large circle of private friends.

WILLIAM ALEXANDER MACKAY, M.D., F.R.C.S. EDIN.

Dr. W. A. Mackay, of Huelva, Spain, who recen died in Ross-shire, was the youngest surviving son the Rev. John Mackay, of Lybster, in Caithn Educated at the Royal High School of Edinbu and at the University, he graduated in medicine 1883, and immediately went to Spain to assist brother, the late Dr. John Mackay, who was c medical officer to the Rio Tinto Copper Compa His surgical skill very early became evident, reputation grew, and he was soon appointed c sulting surgeon to the company, a post he held his retirement in 1926. In 1889 he presented M.D. thesis at Edinburgh on his results in abdomi pelvic, and urinary surgery, and on reading it Lawson Tait at once became his sponsor for elect to the British Gynæcological Society. In the sa year Dr. Mackay became a Fellow of the Ro College of Surgeons of Edinburgh. A prize essay lithotomy and lithotrity made him a correspond member of the Royal Academy of Medicine Surgery of Spain. Some years later he was awar the Military Cross for services rendered to the Spa Civil Guard.

In 1903 Dr. Mackay was joined in partnership Dr. Ian Macdonald, and 20 years later the town Huelva conferred on them its freedom in recogni of their united work in practice and publicati the street leading to their clinic now bears t names. When Dr. Mackay went to Spain special was unknown, and thus the field of his activi always remained wide. "As a surgeon," write medical friend, "he was endowed with the essen qualities of serenity and judgment. In his ea years he operated dexterously for cataract, gradually his work besides general surgery beca more concentrated on the abdomen and pelvis, w as a diagnostician he was rarely in error. He also a particularly safe and rapid operator in ves and urethral lesions. He was an expert accouch too, for he always seemed to judge rightly the t for instrumental assistance to the patient."

His surgical skill was well known in Spain bey Andalusia, but apart from his professional pres he won a unique position in the town where he wor for 40 years. His charm of manner, his im sympathy with the people, his generosity to the p enthroned him in their affections, and among many tributes paid at his death one ended th "Great in his sphere, our town mourns its benefac but the memory of our adopted son endures." Dr. Mackay was a man of wide interests, act speculative, and poetic, and was well read in the lit ture of Spain. He was a staunch president of Huelva Athletic Club for many years, and on the of his funeral in Ross-shire, the teams and specta before a match at Huelva bared heads to his mem He was a keen cricketer and golfer and a good s and he never lost his boyhood's love for fishing.

Dr. Mackay leaves a widow, two sons, and daughters.

THE LATE DR. A. W. WOODROFFE.—Dr. Augu Warren Woodroffe, who died recently at Ticehurst, Su had practised in the neighbourhood for more than 30 y Educated at Trinity College, Dublin, he graduated in and proceeded to the M.D. degree five years later. He for a time medical resident at the City of Dublin Hos and house surgeon at the Peterborough General Hosp He held a number of appointments in the Ticehurst dis and took a great interest in the life of the parish. He been in poor health for two years but was at work on day he died.

Medical News.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE DICAL ASSOCIATION.—From August 29th to Sept. 10th, the Queen Mary's Hospital, Stratford, there will be an day course in medicine, surgery, and the specialties. whole practice of the hospital will be open to those olling. (Fee, £3 3*s.* or £2 2*s.* for either week.) At the hlem Royal Hospital there will be two lecture-demonations bi-weekly from Sept. 6th to Oct. 1st. (Fee £1 1*s.*) m Sept. 12th to Oct. 1st the Royal Westminster thalmic Hospital will hold a course in which clinical ruction will be given daily at 2 P.M., followed by rations at 3 P.M., and special demonstrations three es a week at 5 P.M. (Fee £4 4*s.*) Also beginning on the h, the Queen's Hospital will hold a two weeks' all-day rse. (Fee £3 3*s.*) This hospital specialises in the showing cases rather than on lectures. From Sept. 19th to . 1st a course in orthopædics has been arranged by the yal National Orthopædic Hospital. Lecture-demonstrans will be given daily and the entire practice of the pital will be open to entrants. A special visit will be le to Brockley Hill Country Hospital on one of the urdays. A two weeks' course in medicine, surgery, the specialties will be held from Sept. 19th to Oct. 1st the Westminster Hospital. There will be facilities for ting associated mental institutions. This course and t of the Queen Mary's Hospital are suited to those who h to refresh their knowledge of hospital methods. Copies all syllabuses and of the general course of instruction vided at the associated hospitals, and also of the *t-Graduate Medical Journal* (annual subscription, 6*s.* post), may be had from the Secretary of the Fellowship at Vimpole-street, London, W. 1.

CREMATION OF STILLBORN CHILDREN.—It is understood to be the practice in some maternity institutions to pose of the remains of stillborn children by incineration the premises. In order to remove any misapprehension Minister of Health has drawn the attention of local ervising authorities to regulations which forbid the nation of human remains except in recognised matoriums.

BRITISH SOCIAL HYGIENE COUNCIL.—The executive the British Social Hygiene Council has just concluded annual summer school at Oxford, when a large number delegates attended, representing scholastic, religious, ial, and medical interests in various parts of the Empire. f. J. Arthur Thompson contributed a series of five ures on the Biological Aspects of Modern Sociological ivities, Dr. J. R. Rees expounded the contributions of chology to the practical problems of sex education, le Mr. Z. F. Willis discussed some of the problems of lescence. Other workers dealt with the means of surunting special difficulties in the work of eliminating ereal disease. Next year's summer school will be held Cambridge in the last week of July.

THE LATE DR. E. A. WILLIAMS.—The funeral k place at Chester on August 9th of Dr. Edward Albert lliams, who died in London on August 5th. Educated the King's School, Chester, he studied medicine at nburgh and at St. Thomas's Hospital, London, qualifying L.R.C.P. Edin. in 1906. He took the D.P.H. at Liverpool 910, and before settling for a time in practice at Prestatyn resident surgical officer at Salford Royal Hospital, and ool medical officer under the Liverpool Education committee. During the war he held a captain's commission the Royal Army Medical Corps, later serving with the Army of Occupation on the Rhine. On being demobilised took up bacteriological and radiological work in Paris.

THE LATE DR. H. D. LAWSON.—At the age of 32 Henry Dillon Lawson died on August 4th at the London spital, where he had received his medical education. was the elder son of the late Dr. H. A. W. Lawson, of atford, and joined the army in 1916, serving with a comsion in France. He was twice mentioned in despatches, shortly before the end of the war was recalled to conue his medical studies at the London Hospital. Qualig as M.R.C.S. Eng. in 1922 he was appointed house geon at Torbay General Hospital, but later returned to London Hospital, where he was at first clinical assistant the surgical out-patients' department, and later house sician. His next appointment was to Hanwell Mental spital, and after six months' residence there he worked an assistant in practice at Wadhurst, and then at Shere Surrey. A memorial service was held at Shere on the of the funeral.

A CONVALESCENT HOME TO BE CLOSED.—Queen Mary's Hospital for the East End has reluctantly decided to close its Children's Convalescent Home next spring owing to lack of financial support. The proceeds from the sale of the home will be devoted to the establishment of a Queen Mary's Hospital Convalescent Home Fund, and children will thus be sent to various convalescent homes. The King Edward VII. Hospital Fund for London has made a grant towards the new wing of the hospital, which is to contain beds for casualties. During the year 3039 in-patients were treated.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, August 22nd.—10 A.M., Dr. Dowling: Skin Dept. 2 P.M., Mr. Addison: Surgical Wards. 2 P.M., Dr. Ironside: Medical Out-patient Dept.

TUESDAY.—11 A.M., Mr. Endean: Demonstration of Venereal Cases. 2 P.M., Dr. Shaw: Medical Out-patients. 2 P.M., Mr. Hamblen Thomas: Throat, Nose and Ear Dept.

WEDNESDAY.—2 P.M., Mr. Tyrrell Gray: Operations. 2 P.M., Dr. Scott Pinchin: Medical Out-patients. 2 P.M., Mr. Gibb: Eye Dept.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 11 A.M., Mr. Simmonds: Orthopædic Dept. 3 P.M., Sir Henry Simson: Gynæcological Wards.

FRIDAY.—11 A.M., Dr. McDougal: Electrical Dept. 11 A.M., Dr. Pritchard: Modern Methods in Medicine.

SATURDAY.—10 A.M., Children's Out-patient Dept., Bacterial Therapy Dept.

Operations, Medical, Surgical, and Special Out-patient Departments, daily, 10 A.M. to 5 P.M. Saturdays, 10 A.M. to 1 P.M.

Appointments.

Surgeons under the Factory and Workshop Acts: CHERRY, D. S., M.B., Ch.B. Edin. (Kilbernie, Ayr); WOOD, W. L. R. L.R.C.P. Lond., M.R.C.S. (Ossett, W. Riding).

The Secretary of State for the Home Department announces a vacancy for a Medical Referee under the Workmen's Compensation Act for the Sheriffdom of Lanark. Applications should reach the Private Secretary, Scottish Office, Whitehall, London, S.W. 1, not later than September 3rd.

Births, Marriages, and Deaths.

BIRTHS.

HANSON.—On August 8th, at New King's-road, Hurlingham, S.W., the wife of David C. Hanson, M.C., M.B., of a daughter.

MARRIAGES.

BLACK-MILNE—BENNETT.—On August 8th, at Bournemouth, James Black-Milne, M.D., to Harriet, widow of Arthur Edward Bennett, of Tolles-road, Leicester.

BOURNE—COTONIO.—On August 3rd, at New Orleans, Geoffrey Bourne, M.D., M.R.C.P., to Margherita Cotonio, Ph.D., daughter of Mr. and Mrs. Cotonio, of New Orleans, U.S.A.

DAVIES—BROWN.—On August 9th, at the Friends' Meeting House, Luton, Vyvyan Jeremy Davies, M.R.C.S., L.R.C.P., Swansea, to Margaret Hughes Brown, M.B., B.S., of "Fairholme," Luton.

DONALD—WALKER.—On August 8th, at King's College Chapel, Aberdeen, Charles Donald, F.R.C.S., to Amy Stewart, only daughter of the late Andrew Walker and of Mrs. Walker, Ashley-gardens, Aberdeen.

DEATHS.

CARLÉ.—On August 10th, Frederick Charles Carlé, M.B. Lond., M.R.C.S., L.R.C.P., of "Wayside," West Byfleet, aged 51.

HAMILTON.—On August 9th, at Fenham Hall-drive, Newcastle-on-Tyne, John Hamilton, L.R.F.P.S.G., L.R.C.P.E.

ROUTCH.—On July 18th, at Sermione, Lake Garda, Italy, suddenly, Dr. Frederick Augustus Routch, of Mount Pleasant, Tunbridge Wells, aged 59.

SYMS.—At Selsey, on Aug. 13th, John Kendall Syms, M.R.C.S., L.R.C.P., of Shifnal, aged 51 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstrac

THE HISTORY OF ANGINA PECTOR

HEBERDEN OR ROUGNON?

BY PROF. HANS KOHN,
LIBRARIAN TO THE BERLIN MEDICAL SOCIETY.

FOR more than a hundred years there has been controv as to whether Heberden or Rougnon was the first to nc and describe angina pectoris.

English writers of former times made short work o Gairdner, for instance, described the claims made Rougnon as "an afterthought," and from Gibson they c elicit but "a smile." But more recent authors have ta the matter more seriously. No less a man than Sir Will Osler plainly conceded to Rougnon a priority of s months because his patient had the characteristic sympt of angina—pain and sudden death after emotion. Sir Clifford Allbutt says in his admirable work, "Dise of the Arteries including Angina Pectoris": "It is fai say that although Heberden named the disease and g by far the better description of it, yet the *first* precise cernment and description of it was in a letter by Roug to Lorry . . . ." (The italics are mine.) To reac definite conclusion on the facts seemed to me an ac historical justice. And as my solution is based on entire literature and is unreservedly in the great Bri doctor's favour, it may be that a summary of my conclus will interest English colleagues. They are published detail elsewhere.[1]

Rougnon's Case.

Close study of Rougnon's little book "Lettre à M. Lc etc.," in my opinion leaves hardly any room for d that Rougnon's patient did not suffer from angina pec at all; according to my view of the symptoms and post-mortem findings, he had emphysema of the h leading to gross dilatation of the heart and venous gestion. When moving he complained of "difficulté respirer," little by little increasing to attacks of "suffocat or "oppression" when walking a little hastily or w talking during this exertion. Six weeks before death complained during attacks of "une gêne singulière sur t la partie antérieure de la poitrine en forme de plastr Pain is nowhere mentioned in the actual history of case, though it is true that later, in analysing the sympt singly, Rougnon once employs the word; the patient in his attacks no palpitation but only "une douleur grava dans la région du cœur." Rougnon makes use of expression only occasionally, and—which must not overlooked—lays no stress on this decisive sympt By this "douleur," I feel, he understands nothing bey the "gêne singulière," meaning, I am sure, the quite fam feeling of tightness and even dull pain felt in walking patients suffering from severe dilatation of the he this is a sensation quite different from the subste oppression or excruciating and irradiating pain of an pectoris. Even Baumes, the very discoverer of Roug was obviously of my opinion when saying: "Quoiqu'i ressentît aucune douleur dans la poitrine, etc."

It is true there is very occasionally angina sine dc (Gairdner), but in a case which is supposed to introc a new disease the rule is to be expected, and not the except Moreover, although sudden death *can* be a sympton angina pectoris, such an ending is not at all uncomm after hastily running upstairs, in patients with such enorm dilatation of the heart as the autopsy revealed.

Recognition of a New Clinical Entity.

Even if Rougnon's patient had angina pectoris, bes his emphysema and cardiac dilatation, it is beyond doubt that Rougnon did not recognise it; he saw in case nothing but a grave dyspnœa. Thus he added in no anything to our knowledge of angina pectoris. There v mere descriptions of cases of angina pectoris—and e far more complete ones than his—long before Roug (Willis, Ballonius, Lancisi, Poterius, F. Hoffmann, Morga not to speak of incomplete histories from oldest times); there was an account of post-mortem findings and a v clever explanation by Morgagni, and even an abst conception of the disease, in classical form, by Bartol (1628). All these writers, however, including Bartol (Morgagni renounces classification) saw only dyspnœ their cases, just as Rougnon did, and Heberden's immo merit lies in his having picked out and entirely separ angina pectoris from the, at that time, all-domina dyspnœa. Realisation, consciousness of the new, is necessary condition of every claim to discovery and prio

[1] Zeitschrift für klinische Medicin, vol. cvi., 1927.

nce, according to Claude Bernard, does not consist of
but of conclusions drawn from them.
or the fact that Rougnon did not recognise the disease
hich Heberden gave the name angina pectoris, I found
further striking proofs. In 1788 he published his great
"Considerationes Pathologico-semeioticae de Omnibus
ani Corporis Functionibus," and in this work (fasc ii.,
) he enumerates "dolor pectoris gravativus et obscurus,
doque extensus ad axillas ubi praesertim saevit"—
most conspicious sign of angina pectoris—as the first
ptom of asthma (i.e., bronchial asthma). Again, under
patura cordis" (ib. fasc i., p. 8), he cites a definite
characteristic case of angina pectoris ("hic autem a
o tempore conquerebatur de singulari dolore sub sterno
avis de caetero sanus videretur"), ending in sudden
h after rupture of a coronary artery, without making
slightest allusion to any relation existing between this
and his own described 20 years before.
ougnon's contemporaries, and all the authors till 1808,
ously did not notice a resemblance between Rougnon's
and Heberden's disease. Only by this assumption can
xplain why from its appearance in 1768 nobody took
notice of Rougnon's work until 1808, notwithstanding
fact that it was flatteringly announced in the largely
Journal des Sçavans of July, 1768, where the reviewer
novelty not in the disease described but only in
gnon's explanation—ossification of rib cartilages as
ause of the disorder and sudden death. It is unnecessary
numerate all the other writers who passed over
gnon's work with silence, but one of them should be
ioned—namely, P. C. Marchant, Rougnon's pupil and,
t seems, friend. In Marchant's obituary notice of
gnon (1799) all Rougnon's works are named, singly or
roups, but nothing is said of the famous "lettre"
nothing of Rougnon's part in the discovery of angina
ris, a disease at that time in the very foreground of
al interest. All this shows that Gairdner is right in
g all the claims in Rougnon's favour an afterthought.

The Source of Error.

ugnon's consciousness of having discovered a new
der is sometimes inferred from the title of his work,
cited as "Lettre . . . . sur une Maladie Nouvelle."
Sir William Osler, one of the few who had the rare
in hand, cites it thus. Yet I can say with assurance
this title never existed. I was enabled to examine the
copies that Osler had; they bear the title: "Lettre
. Rougnon, Professeur en Médecine en l'Université de
çon, etc., à M. Lorry, Docteur-Régent de la Faculté
édecine de Paris, touchant les causes de la mort de
Monsieur Charles, ancien Capitaine de Cavalerie,
ée à Besançon, le 23 Février 1768. A Besançon, De
primerie de J. F. Charmet. MDCCLXVIII." There is
ng of "une maladie nouvelle." The title of three other
s I could examine is just the same, and I suppose there
o more existing copies anywhere. Baumes gave the
title; Desportes and Jurine, the next writers
eviated it to "Lettre à Lorry," and this seems to have
too devoid of substance to Pinel and Bricheteau,
ng them to add "sur une maladie nouvelle." (Pinel
Bricheteau admitted that they had not themselves
the book.) This is the source of error.

Conclusion.

sum up: in my opinion and that of Gairdner Rougnon's
nt did not have angina pectoris at all. Supposing,
ver, that it was a case of angina, Rougnon's description
by no means the first. Furthermore, although he
ibed *a case*, he failed to see anything else in it beyond
nœa. Heberden, on the contrary, did not describe
ase but conceived from 20 cases, by ingenious intuition,
bstract picture of the disease. He drew its features
ch a way as to leave little for later clinicians to add;
netrated deeply into the pathogenesis of the condition,
g an explanation (spasm, although not determining
at) subsequently more and more confirmed; he laid
the prognosis; and in the form of opium, he gave
pasmodic treatment which to-day is still regarded
e essential.
here any possibility of doubt as to whom priority is due?

EARLY BOOKS ON MEDICINE.

OM Lugano there reaches us the second part (E–L)
e catalogue of "Early Books on Medicine, Natural
ces, and Alchemy," issued by L'Art Ancien S.A.,
rs in rare books. Lugano is a tri-lingual centre in touch
the forgotten hill-top libraries of Italy and the monas-
of the Near East, from which many of the treasures
offered must at various times have been drawn. One
e most curious is the "Tacuini sex rerum non natural-
" of Elimithar, the Arabic savant, published at Strassburg
hott, the printer, in 1533. The book is notable for its
delicate woodcuts by Hans Weiditz, illustrating, among other things, the appearance of plants with a signaturist significance. Some seeds or nuts are representative of brains, testicles, the heart, and so forth, and from them were derived medicines destined to cure the diseases of those organs in man. In the same folio, bound in old vellum and offered for 375 Swiss francs, is the companion work by Bengesla entitled "Tacuini Aegritudinum et Morborum," which is especially interesting for the delicate marginal woodcuts illustrative of the daily domestic life of the sixteenth century. These are also by Weiditz, who has drawn objects of daily use—tools, furniture, utensils, and costumes—still employed by the peasantries of central Europe. Very curious are the cuts representing the routine of bagnios and houses of ill-fame. The book is one of those discussed by Choulant in his well-known work on anatomical illustration. Sir Thomas Elyot's "Castel of Helth," printed in London by Thomas Berthelet in 1541, is the very rare early edition, here valued at fr. 1000. Elyot was a layman, but his learning was profound, and his book, though decried by the medical profession of his time, remained the popular medical text-book of the age of Henry VIII. and his Tudor successors. Two works by the Abbé Charles-Michel Epée on deaf-mutes are offered at moderate prices. These are his "Institution des Sourds et Muets par la voie des signes méthodiques," Paris, 1776, and "La véritable manière d'instruire les sourds et muets," Paris (Lyon), 1784. Epée was the founder of the first institute for the deaf and dumb in Paris in 1755, and was himself the immediate continuator of the work of Rodriguez Pereira.

Rare works by Eustachius, Fallopius, Fracastorius, and Galen also figure in this catalogue. "The Passionarius Galeni" of Gariopontus, published at Lyons in 1526, is particularly worthy of notice, the price being fr. 275. This once-famous work by the earliest Salernitan teacher is a compilation of translations from Græco-Byzantine authors, and is a compendium of early eleventh century knowledge of medicine. As many as five ancient editions of the "Hortus Sanitatis" are in the catalogue, as well as the curiously illustrated works of Ketham and the medical tractates of Lactantius, the Christian father Lancisi, Martin Lister, and many other famous physicians and surgeons.

ORANGES IN CHICAGO.

EVERY week the Chicago Department of Health publishes a bulletin, and a recent issue was devoted entirely to the subject of oranges. Full of that "pep" which "orange juice gives you," the leaflet on every page contains attractive sketches illustrating such truths as "oranges for heat and energy," "oranges for vigorous leadership," "oranges for dash and daring"—Colonel Lindberg chose to drink it at the end of his Transatlantic flight—and "orange juice is not fattening" (illustrated by a picture of a fashionable girl in a fashionable pose). Although there is an accurate statement of the value of oranges in the dietary, the untrained reader may well imagine that all he needs is oranges, oranges all the way, to set him up in health for ever. Accustomed, however, to these weekly exhortations, the Chicago citizen will doubtless take them with a pinch of salt, and it must be admitted that the pamphlet is more attractive than anything produced in this country as health propaganda. Dr. Herman Bundesen's weekly bulletin is an instructive example of American enterprise in "advertising health," and this is a specialty which is likely to receive increasing attention on this side of the Atlantic. Certainly the "eat more fruit" campaigners must be grateful to Chicago's Public Health Department.

MEMORIES OF WAR WORK.

THE title of an unpretending little book[1] is taken from the list of offices in the Church given in the first Epistle to the Corinthians, chap. xii. The object of its publication is primarily to make some money towards meeting the expenses of the Pelham Memorial Hall in the parish of Holy Trinity, Norwich, and secondarily to put on record the experiences of at least one of the army of mainly unknown workers who did their best when their country was in sore straits. Mrs. Bulstrode, in the early days of the war, before the formation of the W.A.A.C., offered herself for any kind of war work, and after a period of intensive training was admitted as a hospital nurse. She worked at first in a hospital on Salisbury Plain and later at one on the South Coast, and at an internment hospital in Switzerland, ending up with a post in the massage department of one of the big London general hospitals. As a record of the impressions produced upon one who went into hospital work unversed in the experiences which she was going to meet, this little book is of interest. The smile and the tear are, as everyone knows, very near together in hospital work, and Mrs. Bulstrode shows that she managed to appreciate both at their proper values.

[1] Some . . . . Helps: Memories of War Work at Home and Abroad. By Frances J. Bulstrode. Norwich: Jarrold and Sons, Ltd. 1927. Pp. 62. 1*s.* 6*d.*

SUN-BATHING IN HYDE PARK.

A MAN of 44, who had apparently been sun-bathing in Hyde Park, was bound over by the magistrate at the Marlborough-street Police-court on August 12th, on a summons for contravening the regulations scheduled in the Parks Regulation Act of 1872. The newspaper report of the case did not specify the precise offence alleged; presumably the prosecution relied upon Regulation 14 in the schedule: "No person shall commit any act in violation of public decency, or use profane, indecent or obscene language to the annoyance of other persons using a park." Though the punctuation is misleading, the regulation probably means that the act violating public decency (as well as the profane, indecent or obscene language) must be to the annoyance of others. In certain parts of the continent the standard of public decency tolerates considerable concessions to the pursuit of health by exposure to the sun's rays. It was contended on behalf of the accused in the case under discussion that exposure of the upper part of the body for the purpose of benefiting health was not a violation of public decency. The magistrate (Mr. Mead) said he thought decent people—not prudish people—would be shocked to see a man ostentatiously sprawling about on the grass as the accused was doing. He also expressed apprehension of what might happen if myriads of people of both sexes in Hyde Park acted in a similar way. The accused, he said, could carry out his ideas of health under proper conditions without restraint.

The law of our parks is a little obscure. The Act of 1872 dealt only with certain specified Royal parks and gardens, mostly in the London district. The regulations scheduled to the Act covered such matters as dangerous driving, drilling, practising gymnastics, public speaking, drunkenness, discharging firearms, lighting bonfires, flower-picking, dog contol, fishing, bathing, and skating. Some of these regulations could be amplified by "rules of the park" made by the Commissioners of Works. Such rules were made for Hyde Park in 1910 and again in 1926. The rules deal with vehicle traffic, processions, public addresses, bathing, and boating. Bird's-nesting is forbidden; so is fishing in the Serpentine; so also is the loitering of unclean or verminous persons in the park or their lying on the ground or occupation of seats. Last year the Parks Regulation (Amendment) Act extended the statute of 1872 to all open spaces under the control of the Office of Works, and removed any restriction of the statute to merely "Royal" parks. The Commissioners of Works will in future be allowed to make regulations for all such places, and the regulations scheduled to the 1872 Act are repealed as from December next. Battersea, Victoria, and Kennington Parks were transferred to the charge of the Metropolitan Board of Works in 1887, and are thus now controlled by the London County Council. The Royal Botanic Gardens at Kew have been under the control of the Board, now the Minister, of Agriculture since 1889. The upshot of the legal developments of park regulation is a diversity of authorities and of laws. It would be safe to say that few persons who use Hyde Park are aware of the offences they may be committing, though indecent exposure is, of course, punishable by the general law of the land as well as by the local park regulations.

HEALTH CONDITIONS IN HONG-KONG.

A DELAYED report on the affairs of Hong-Kong for the year 1925, prepared by the Colonial Secretary, has been issued as a Parliamentary paper. It states at the outset that 1925 was not a happy year for the colony, owing to the great strike and other circumstances, though the manner in which it weathered the storm was a matter of self-congratulation for all sections of the community. The estimated total population at the middle of the year under review was 874,420, but this includes the New Territories, and, as the birth and death figures given below do not include those from this area (with the exception of New Koolon), the population for the purpose of calculating these rates was estimated at 786,920, of whom 16,500 were non-Chinese. The birth-rate for the year was 4·25 per 1000 among the Chinese community, and 22·6 per 1000 among the non-Chinese community, as compared with 5·47 and 18·25 for 1924. The figures for the Chinese community are obviously misleading owing to defective registration. The death-rate for the year was 19·12 per 1000 among the Chinese community, and 14·6 among the non-Chinese civil community, as compared with 21·9 and 15·68 for 1924. The following is a complete return of the deaths registered in the colony during the year: hydrophobia, 3; influenza, 45; small-pox, 41; measles, 3; typhoid fever, 91; diphtheria, 38; cerebro-spinal fever, 57; dysentery, 331; plague, nil (the last deaths from plague occurred in 1923); malarial fever, 702; cholera, 2; puerperal fever, 3; septic infections, 56; syphilis, 376; poisoning 74; injuries, 366; developmental diseases, 293; old age, 577; general tuberculosis, 253; beri-beri, 1744; cancer, 116; paralysis and convulsions, 110; heart disease, 202; pneumonia, 2878; phthisis and pulmonary tuberculosis, 1831; enter and gastro-enteritis, 1080; cirrhosis of liver, 35; peritoni 28; nephritis, 433; other causes, 2931; unknown, 292

Civilian Hospitals.

The Civil Hospital contains 198 beds in 23 wards. 5 in-patients and 30,889 out-patients were treated du 1925, as against 6406 and 31,347 respectively in 1924. maternity hospital contains nine beds for Europeans, 1 three extra beds, and eight for Asiatics; 668 confinem occurred during the year, as against 789 in 1924. Victoria Hospital at the Peak contains 41 beds, and du 1925 320 patients were under treatment there. At Kenn Town Hospital, which contains 26 beds, 12 cases were trea in 1925, being infectious. The Kimatu Asylum is under direction of the superintendent of the Civil Hospi European and Chinese patients are separated, the Europ portion containing 14 beds in separate wards, and the Chi portion 16 beds. 308 patients of all races were treated du 1925, and there were nine deaths.

The Tung Wa Hospital, opened in 1872, is ma supported by the voluntary subscriptions of Chin only Chinese are treated in this institution, which perfo various other services not appertaining to a hospital, s as the free burial of the poor, the repatriation of destitu the maintenance of free vernacular schools, and organisation of charitable relief in emergencies; Chines well as European methods of treatment are employe accordance with the wishes expressed by the patient their friends; over half the number are now treated Western methods. There are 450 beds in the building, 9133 patients were accommodated during 1925. institution is under the supervision of a visiting physic who is a member of the medical department, whilst Chinese house surgeons, trained in Western medicine, members of the hospital staff. The Tung Wa also main a branch hospital for small-pox cases (Chinese only Kennedy Town. It contains 70 beds, and during 23 cases were treated.

The Alice Memorial and Affiliated Hospitals dealt 1402 in-patients in 1925 and 81,715 out-patients. Kwong Wa Hospital for Chinese in the Kowloon Penin was opened in 1911. It occupies a site having an are three acres, and the existing buildings contain 215 b 6862 patients were accommodated during 1925.

Dispensaries.

Amongst other institutions in the colony supported voluntary contributions is the Pó Leung Kuk, a Chi society for the suppression of kidnapping and traffi human beings, and the Eyre Diocesan Refuge, founded rescue work among the Chinese. The Chinese pu dispensaries are institutions maintained in order to pro the Chinese with the services of doctors whose certific will be accepted by the registrar of deaths, and with services of interpreters who can assist the inmates of ho where a case of infectious disease has occurred. Coolies engaged, and ambulances and dead vans provided in o to remove cases of infectious disease to the infectious dise hospital, and dead bodies to the mortuary. The dispens receive sick infants, and send them to one or other of convents, and arrange for the burial of dead infants. advice and medicine are given, and patients are atte at their houses.

THE BALANCE-SHEET OF SUNSHINE CLINIC

EXPERIMENTAL light centres were established at Ashton-under-Lyne and Lancaster County dispensarie 1925 for the treatment of certain forms of non-pulmo tuberculosis. A report by Dr. G. Lissant Cox to the Co Council states that the treatment has given good re in two groups of cases refractory to other forms of t ment—namely (1) lupus, and (2) adenitis with ab formation and skin involvement. Many of the lupus had been under treatment for 20–40 years prior to mencing light treatment. The efficiency of light treatm was not so strikingly proved in other types of sur tuberculosis which respond fairly satisfactorily to forms of treatment.

No permanent ill-effect, either local or general, had caused by artificial light treatment and no patient tre by light had relapsed. Dr. Cox informed the health comm that the total number of cases of non-pulmonary t culosis in the county of Lancaster on Dec. 31st, 1926, 3708, of whom 1219 were likely to benefit by light treatm After a careful review the committee came to the clusion that the provision of light apparatus shoul considered for 15 of the existing county dispensaries as to make it possible to treat patients reasonably ne their homes. Cost and saving might be set out t Estimated cost (including depreciation at one-fifth of ca cost of £1950) of running 15 centres for one year, £ Estimated saving (based on experience at Ashton) in of residential and other special treatment by attendan patients at centres, £6000.

THE CONDUCT OF MEDICAL PRACTICE

BY

THE EDITOR OF "THE LANCET" and Expert Collaborators

The book is a guide to the conduct of medical practice in all its shapes. It deals with the medical career generally—with the circumstances which should influence the student's decision to adopt one or other of its branches, and with the various situations in which the medical practitioner is placed, both in the establishment of himself in a practice and in carrying it on with regard for his public obligations and his professional responsibilities.

STUDENTS' GUIDE—SESSION 1927-1928.

ENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

POWERS, DUTIES, AND CONSTITUTION.

THE General Council of Medical Education and gistration of the United Kingdom is, first, a istering body: no person, even though his qualifications have been obtained by examination, is a *legally ulified* medical practitioner until his name appears the Medical Register. Secondly, it is a standardis- body, ensuring that medical education reaches an cient standard by scientific examination. Thirdly, s a penal and disciplinary body, having power to nove from the Register any practitioner convicted felony or misdemeanour or adjudged guilty of ofessional misconduct. Fourthly, to the Council is nmitted the codification of pharmaceutical remedies. e duties of the Council are thus primarily of a blic nature, and its construction shows its fitness its fourfold responsibilities.

The Council consists of 38 members, of whom all t 11 are official representatives of some corporate dy. Five members are chosen by the Crown on the vice of the Privy Council, and six others are elected the members of the medical profession as Direct presentatives. The Crown members need not be dical men and one layman now sits on the Council. ree members are appointed for dental business by Privy Council under the Dentists Act, 1921, der which the powers and duties of the General dical Council with regard to the keeping of the ntists Register and the administration of the ntists Acts were largely transferred to the Dental ard of the United Kingdom.

THE EDUCATIONAL CURRICULUM.

Professional Education.—The course of professional dy after registration occupies at least five years. e Final Examination in Medicine, Surgery, and dwifery must not be passed before the close of the h academic year of medical study.

Regulations as to Registration of Medical Students.

Before registration every candidate should produce dence that he has attained the age of 17 years. e minimum standard of General Education uired is that of University matriculation or rance examination in the Faculties of Arts or Pure ence. In other Faculties the examination must be the standard prescribed in Regulation 2 below. fore registration as a student every applicant uld be required to have passed a recognised mination in general education, and, in addition reto, an examination, theoretical and practical, elementary physics and elementary chemistry ducted or recognised by a licensing body.

An approved course of instruction in elementary logy at a secondary school or other teaching titution recognised by a licensing body may admit udent to the professional examination in elementary logy upon registration as a medical student.

The candidate commencing medical study should ply to the registrar of the division of Great Britain l Ireland in which he is residing, according to a scribed form, copies of which may be had on plication to the several licensing bodies, medical ools, and hospitals, or at the offices of the Council; l should produce proof that he or she has fulfilled first three conditions.

he Maintenance of the Register of Medical Students.

. The Education Committee prepares and issues m time to time a list of examining bodies whose minations in general education fulfil the conditions and are specially recognised by, the Council.

2. The Council has recognised the undernoted university examinations which are conducted in Great Britain and admit to the Faculties of Arts or Pure Science, or to other Faculties, subject to the conditions specified below:—

Birmingham University, Matriculation Examination. Bristol University, Matriculation Examination. Cambridge University, Previous Examination. Durham University, Matriculation Examination. Leeds University, Matriculation Examination. Liverpool University, Matriculation Examination. London University, Matriculation Examination. Manchester, Victoria University, Matriculation Examination. Oxford University, Responsions. Scotland, Universities of, Entrance or Preliminary Examination. Sheffield University, Matriculation Examination. Wales, University of, Matriculation Examination.

The condition prescribed by the Council in Faculties other than Arts or Pure Science is that:—

The certificate shall bear evidence that the candidate has passed in the following subjects, viz.: (*a*) English. (*b*) Mathematics, Elementary. (*c*) A language other than English. (*d*) A fourth subject, as defined in the regulations of the particular Examination, to be chosen from the subjoined list, viz.: History, Geography, Physical Science, Natural Science; Latin, Greek, Hebrew, French, German, or other language accepted by the University for the purpose of matriculation or entrance.

3. Subject to the condition prescribed above (Section 2), the Council will recognise those of the examinations conducted by recognised authorities in Great Britain which are accepted by any one or more of the above-named Universities as equivalent (under prescribed conditions as to "credits" or "grades"), for purposes of Entrance or Matriculation, to an Examination named in the preceding list (Section 2). Such Examinations are:—

Bristol University: High School Certificate Examination; Schools Certificate Examination. Cambridge Local Examinations Syndicate: Higher School Certificate Examination; School Certificate Examination. Central Welsh Examination Board: Higher Certificate Examination; School Certificate Examination. Durham University: Higher Certificate Examination; School Certificate Examination. London University: Higher School Certificate Examination; General School Examination. Northern Universities Joint Matriculation Board: Higher Certificate Examination; School Certificate Examination. Oxford and Cambridge Schools Examination Board: Higher Certificate Examination; School Certificate Examination. Oxford Delegacy for Local Examinations: Higher School Certificate Examination; School Certificate Examination. Scottish Education Department: Leaving Certificate Examination.

4. The Council will continue to recognise certain Examinations conducted by Educational Bodies, other than those (mentioned in Section 3) whose Examinations are accepted by any one or more of the Universities of Great Britain. Recognition will not be extended under this Section to any Examination unless the Council is satisfied (*a*) that in scope and standard it is equivalent to a recognised Matriculation or Entrance Examination of a University of Great Britain, (*b*) that it fulfils the condition prescribed by the Council (Section 2), and (*c*) that the Examination has been completed at not more than two sittings. Such Examinations are:—

The College of Preceptors (England): Senior Certificate. The Educational Institute of Scotland: Preliminary Medical Certificate.

5. Subject to the prescribed condition (Section 2), the Council will recognise the Entrance Examination to the School of Physic of the University of Dublin, and the Matriculation or Entrance Examinations of the National University of Ireland, the Queen's University of Belfast, the Irish Royal Colleges of Physicians and Surgeons; and also the Leaving Certificate of the Intermediate Education Board of the Irish Free State, the Senior Grade Leaving Certificate of the Ministry of Education of Northern Ireland, and all examinations accepted by any one or more of the Universities of Great Britain or Ireland

as equivalent, for purposes of entrance or matriculation, to the above-named University Examinations.

6. Subject to the prescribed condition (Section 2), the Council will recognise all Examinations of Colonial or Foreign Universities which are accepted by any one or more of the Universities of Great Britain as equivalent, for purposes of entrance or matriculation, to an examination named in the list of examinations recognised by the Council (Section 2).

7. The Council will recognise the Final Examinations for Degrees in Arts or Science of any University of Great Britain or Ireland or of the British Dominions.

8. The registration of medical students shall be placed under the charge of the Branch Registrars.

9. Each of the Branch Registrars shall keep a register of medical students.

10. The Branch Registrar shall enter the student's name and particulars in the Students Register, and give him a certificate of such registration.

11. Each of the Branch Registrars shall supply to the several licensing bodies, medical schools, and hospitals, in that part of Great Britain or Ireland of which he is Registrar, blank forms of application for the registration of medical students.

12. A copy of the Medical Students Register prepared by each of the Branch Registrars shall be transmitted, on or before Dec. 31st in each year, to the Registrar of the General Council, who will distribute the list to the licensing bodies, medical schools, and hospitals.

All applications for special exceptions to the foregoing regulations as to registration shall be addressed to the Registrar of the General Council, and shall be decided by authority of the Education Committee, who shall report thereon to the Council.

The Medical Schools and Colleges.

The Universities, including their Colleges and Medical Schools, and Schools of Medicine at which Medical Study may be commenced in the United Kingdom are set out seriatim in the following pages.

MEDICAL REGISTRATION IN IRELAND.

Within the past few months the problem of medical registration in the Irish Free State, which had given rise to some anxiety during the past two years, has been satisfactorily settled. By agreement between the Governments of Great Britain, of the Irish Free State, and of Northern Ireland—since confirmed by legislature at Westminster and Dublin—the powers and duties of the General Council of Medical Registration and Education are to continue as heretofore in respect of qualifying bodies in the Irish Free State, and of medical practitioners qualified in the Irish Free State. Side by side with this a Medical Council is to be set up in the Irish Free State with the duty of establishing and controlling a Register for the Irish Free State. All practitioners whose names are on the General Register at the moment, whose address therein is given as being in the Irish Free State, will in the first instance be entered on the Irish Free State Register; practitioners whose names are on the General Register, but who are resident outside the Irish Free State, will also be registered if they apply within one month before the establishment of the Register. After the establishment of the Register practitioners whose names are on the General Register, and persons who pass a qualifying examination in the Irish Free State, will be registered on payment of the prescribed fee. The Irish Free State Medical Council will have, over those whose names are on the Irish Free State Register, the same disciplinary powers as are possessed by the General Council over those whose names are on the General Register. To possess the privileges of a qualified practitioner in the Irish Free State it will be necessary to be registered in the Irish Free State Register.

The net result of the change in the law as regards the practitioner qualifying in the Irish Free State in the future is that: (1) If he intends to practise only in the Irish Free State he need only register in the Irish Free State Register; (2) if he intends to practise in Great Britain he will register in the General Register; and (3) if he is in doubt where he will practise he will register in both Registers. He will, as he registers in one Register, or in both Registers, put himself under the disciplinary control of the Irish Council or of both Councils. No practical inconvenience is caused, and practitioners qualified in the Irish Free State in future will not find themselves deprived of any of the privileges or rights enjoyed by their predecessors.

THE DENTAL BOARD OF THE UNITED KINGDOM

Anyone who is on the Medical Register is entitled to practise as a dentist, although he cannot register as such without degree or licence in dentistry; but it is a distinct advantage to take a special dental qualification, otherwise few dental appointments at general or special hospitals or dispensaries are available.

Under the Dentists Act, 1921, the powers and duties of the General Medical Council under the Dentists Act, 1878, and under the Medical Act, 1886, which related to the keeping of the Dentists Register and the administration of the Dentists Acts were largely transferred to the then newly-constituted Dental Board of the United Kingdom. The registration of dental students at the commencement of their dental studies, and the right of erasure of a name from the Dentists Register, remain with the Council, but the duty of inquiring into disciplinary cases rests with the Board, upon whose recommendations the Council acts.

The Dental Board consists of a chairman and 25 members. The chairman is appointed by the Privy Council. Other members of the Board are appointed by the Minister of Health, the Scottish Board of Health, the Governor-General of Northern Ireland, the General Medical Council (3), Direct Vote of the qualified dentists practising in England and Wales, Scotland, and Ireland (3), Direct Representatives of registered dentists not being qualified dentists (2).

Registration of Dental Students.

The General Medical Council's Regulations in regard to the registration of dental students which came into force on Jan. 1st, 1923, provide that the registration of dental students shall be carried on at the General Medical Council Office in London, in the same manner as that of medical students, and be subject to the same regulations as regards age and preliminary examinations; but in the case of dental students professional study may commence either at a recognised dental hospital or school, or by pupilage with a registered dental practitioner.

Candidates for a diploma in dental surgery should produce certificates of having been engaged for at least four years in professional studies, and of having received during 24 calendar months instruction in dental mechanics. It is recommended that instruction in dental mechanics be taken at a recognised dental hospital and school. If any part of such instruction be taken by the candidate as a pupil with a registered dental practitioner, the time required to be devoted to it shall be at least twice the time required for the corresponding instruction taken at a dental school. Two years' bona-fide apprenticeship with a registered dental practitioner, after registration as a dental student, may be counted as one of the four years of professional study. The necessary instruction in dental mechanics, or any part of it, may be taken by the dental student either before or after his registration as a student. When a student can show evidence of regular pupilage in dental mechanics to a registered dental practitioner, prior to the passing of the prescribed preliminary and scientific examinations, he may be allowed to antedate his registration for a period not exceeding one year prior to the passing of these examinations.

THE OFFICES.

The address of the Registrar, to whom further communications should be addressed, is as follows: The Registrar of the General Medical Council, 44, Hallam-street, Portland-place, London, W. The offices of the Dental Board are adjoining.

THE MEDICAL EXAMINING BODIES AND SCHOOLS OF THE UNITED KINGDOM.

GUIDE TO THE FACILITIES FOR OBTAINING THE VARIOUS MEDICAL DEGREES AND OTHER QUALIFICATIONS FOR THE BRITISH MEDICAL REGISTER.

I.—ENGLAND AND WALES.

THE UNIVERSITIES.

UNIVERSITY OF OXFORD.

THERE are two degrees in Medicine, *B.M.* and *D.M.*, in Surgery, *B.Ch.* and *M.Ch.*, and diplomas in *Public Health and Ophthalmology.*

Only Graduates in Arts of the University are eligible for the Medical and Surgical degrees. The most convenient course for the B.A. degree for intending graduates in Medicine is to take Responsions, the Preliminary Science Examinations mentioned below, and the Final Honour School of Physiology. To obtain the degrees of B.M. and B.Ch. the following examinations must be passed: 1. Preliminary Subjects: Physics and Chemistry, Zoology, and Botany. 2. Professional. (*a*) First Examination: Subjects—Organic Chemistry, unless the candidate has satisfied the examiners in Part I. Chemistry in the Honour School of Natural Science; Human Physiology, unless he has obtained a First or Second Class in Animal Physiology in the Honour School of Natural Science; Human Anatomy. (*b*) Second Examination: Subjects—Medicine, Surgery, Midwifery, Pathology, Forensic Medicine with Hygiene, Materia Medica and Pharmacology. The First and Second Professional examinations are held in June and December. The first B.M. examination may be passed at any time after the Preliminary Scientific examinations. Anatomy and Physiology must be passed at the same time—Organic Chemistry may be taken separately.

At any time after passing *First B.M. Examination*, a candidate can, on producing certificates, present himself for examination in the subjects of Pathology, Forensic Medicine with Hygiene, Materia Medica and Pharmacology; but cannot, unless he is already a registered medical practitioner, enter for examination in Medicine, Surgery and Midwifery until the eighteenth term from his matriculation, nor until a period of at least thirty-three months has elapsed from the date of passing the First B.M. Examination. He must pass in Medicine, Surgery and Midwifery at one and the same time.

Before admission to the Examinations in Pathology and Bacteriology, and Materia Medica and Pharmacology, of the second B.M. Examination, the student must produce certificates of having attended courses of instruction including practical work in Pathology, Bacteriology, Post-Mortem Clerking, Pharmacology, and Pharmacy, either in Oxford or in a recognised Medical School. Before admission to the remainder of the second B.M. Examination, he must produce a number of other certificates, including certificates of having acted as Clinical Clerk and Dresser, each for six months in the Wards, of instruction in Midwifery and of attendance on Labours, of instruction in Infectious Diseases and in Ophthalmology, of proficiency in Vaccination and in the administration of Anæsthetics, and of three academic years of hospital practice.

The degree of B.Ch. is granted with that of B.M. to all passing the above examinations. The degree of D.M. is granted to Bachelors of Medicine of the University who have entered upon their thirtieth term from Matriculation, and have submitted a dissertation which is approved by the examiners for the B.M. degree whose subjects are dealt with therein and by two Professors in the Faculty of Medicine. The degree of M.Ch. is granted after examination to Bachelors of Surgery in the University who have entered upon their twenty-first term, and who are Members of the Surgical Staff of a recognised hospital, or have acted as Dresser or House Surgeon in such a hospital for a period of six months. The examination, which includes Surgery, Surgical Anatomy and Pathology and Surgical Operations, is held annually in June, after the Second B.M. examination.

The examinations for the Diploma in Public Health in two parts are held in Trinity and Michaelmas terms; that for the Diploma in Ophthalmology is held annually in July.

Travelling Fellowship, Scholarships, and Prizes.—A Radcliffe Travelling Fellowship is awarded annually after an examination held in February. It is tenable for two years and of the annual value of £300. The examination is in Physiology, Pathology, and Hygiene, and is partly "practical." Candidates must be graduates in Medicine of the University. The holder must travel abroad for the purpose of medical study. Application should be made to the Radcliffe Examiners, Department of Medicine, University Museum. A Christopher Welch Scholarship of £100, tenable for four years, is awarded annually after examination. Candidates must be men undergraduate members of the University, who have not exceeded the twelfth term from their matriculation, or been admitted to any degree in the University. They may offer any one of the subjects, Animal Physiology, Botany, Zoology. A George Herbert Hunt Travelling Scholarship of the value of about £100 is awarded every second year to enable a Bachelor of Medicine to undertake three months' study abroad. A Rolleston Memorial Prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing for an original research in some Biological subject, including Physiology or Pathology. The Radcliffe Prize, founded by University College (1907). is of the value of £50 and is awarded biennially (alternating with the Rolleston Memorial Prize) for research in some branch of medical science. The Theodore Williams Scholarships, each of the value of £50 a year for two years, are awarded annually in the subjects of Anatomy, Physiology, and Pathology. A Radcliffe Scholarship in Pharmacology, of the value of £50 for one year, is awarded annually by the Master and Fellows of University College. A King's College Hospital Burney Yeo Scholarship of £80 is awarded each year on the nomination of the Regius Professor of Medicine. The Scholarships and Exhibitions in Science which are offered by most Colleges are open to those who intend to pursue Medicine. The value of these scholarships is usually £80 a year for four years; the exhibitions vary in value from £30 to £90 per annum. The number of scholarships and exhibitions in Science offered annually is about forty. There are also Medical Scholarships of the value of £100 a year at University College and at Pembroke College. The Welsh Memorial Prize for Anatomical drawing is awarded annually, and is of the value of about £10.

Post-graduate courses are held at the beginning of October. In the course of the past year large new Departments of Biochemistry, Pathology, and Pharmacology have been brought into use; the Department of Physiology has been considerably enlarged by the removal of Biochemistry to a separate building; and the laboratories of Anthropology attached to the Department of Human Anatomy have been greatly extended.

More detailed information may be obtained from the University Calendar; from the Examination Statutes, 1923; from the Regius Professor of Medicine; from the Professors in the departments of medical science; and from the Dean of the Medical School, Oxford.

UNIVERSITY OF OXFORD: RADCLIFFE INFIRMARY AND COUNTY HOSPITAL.—225 beds. Courses of instruction are given in connexion with the Oxford University Medical School. These include (1) a course

in Practical Medicine by the Regius Professor of Medicine; (2) clinical lectures by the Litchfield Lecturers in Medicine and Surgery; and (3) tutorial instruction and demonstrations in special Regional Anatomy (medical and surgical), methods of Medical and Surgical Diagnosis, and Surgical Manipulation. (4) Pathological demonstrations and instruction in post-mortem work are given by the Assistant Pathologist. Opportunities are offered to students who wish to act as surgical dressers and clerks. A post-graduate course is held in the hospital in the autumn of each year.

UNIVERSITY OF CAMBRIDGE.

The student must enter a College, or as a non-collegiate student, and keep nine terms (three years) by residence. He must pass the Previous Examination of the University before he comes into residence or he may obtain exemption through the Oxford and Cambridge Schools Examination Board, the Oxford or Cambridge Senior Local Examinations, the London Matriculation Examination, the Scotch Education Department, Responsions at Oxford, and the Joint Matriculation Board of the Universities of Manchester, Liverpool, Leeds, and Sheffield, the Matriculation Examination of the University of Birmingham, and certain other certificates, or by being a graduate of certain other Universities in the United Kingdom. He may then devote himself to medical study in the University, &c. Or he may, as nearly all students now do, proceed to take a degree in Arts by passing the Examinations for the ordinary B.A. degree, or an Honours degree by passing a Tripos Examination. The Natural Sciences Tripos is taken most frequently by medical students, as some of the subjects are practically the same as those for the First and Second M.B. examinations.

For the degree of *Bachelor of Medicine* (*M.B.*) five years of medical study are required either in Cambridge or at one of the recognised Schools of Medicine. The first three or four years are usually spent in Cambridge till the student has passed the examination for Part I. of Natural Sciences Tripos and the First and Second examinations for M.B. Hospital practice may be attended in Cambridge, but until the student has completed the course for the third part of the second M.B. it cannot count towards the two and a half years of hospital practice required before admission to the first part of the Third M.B. The laboratories for Botany, Chemistry, Physics, Biology, Zoology, Human Anatomy, Physiology, Biochemistry, Pathology, Bacteriology, Pharmacology, Psychology, and Public Health are well equipped. Addenbrooke's Hospital, the Infectious Diseases Hospital, the Cambridge Research Hospital, and the Field Laboratories are utilised for study and research.

There are three examinations for M.B. The *first* includes (1) General and Inorganic Chemistry, (2) Mechanics, (3) Physics, and (4) Elementary Biology. These parts may be taken together or separately. The *second* is divided into three parts—viz. (1) Organic Chemistry, (2) Human Anatomy and Physiology, and (3) Pharmacology and General Pathology. The *third* is divided into two parts: (1) Principles and Practice of Surgery (including Special Pathology and Midwifery and Diseases Peculiar to Women); and (2) Principles and Practice of Physic (including Diseases of Children, Mental Diseases, Medical Jurisprudence), Pathology (including Hygiene and Preventive Medicine), and Pharmacology (including Therapeutics and Toxicology). The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting room, and in the laboratories. An Act has then to be kept by the candidate reading an original dissertation composed by himself and being examined orally on some subject approved by the Regius Professor of Physic. Candidates who have passed both parts of the third M.B. examination are admitted to the registrable degree of *Bachelor of Surgery* (*B.Chir.*) without separate examination and without keeping an Act.

The degree of *Doctor of Medicine* (*M.D.*) may taken three years after that of M.B. or four years af that of M.A. The candidate is required to prod certificates of having been engaged in Medical Stu for five years, and if an M.A. to pass the same exa nations as are required for the degree of M.B. An has to be kept, consisting of an original Thesis w *viva voce* examination; and a short extempore es has to be written on a topic taken from the gene subject of his thesis, whether it be Physiolo Pathology, Pharmacology, the Practice of Medici State Medicine, or the History of Medicine.

For the degree of *Master of Surgery* (*M.Chir.*) candidate must have passed all the examinations B.Chir., or, if he is an M.A., have obtained some ot registrable qualification in surgery. He is required pass an examination in Principles and Practice Surgery, Surgical Anatomy and Surgical Operatic and Pathology, and to write an extempore essay a Surgical Subject. Before he can be admitted the examination two years at least must have elap from the time when he completed all required for degree of B.Chir.

Diplomas are granted in Public Health, Hygiene, in Tropical Medicine and Hygiene, and Medical Radiology and Electrology. Candidates m hold a recognised medical qualification. (See p. 4

Women Students.—Increased facilities have b offered to students of Girton and Newnham Colle and they are admitted to the M.B. Examinations.

Scholarships and Prizes.—Medical studies endowed by the numerous Natural Science schol ships at the various colleges, information about wh can be obtained from the respective Tutors. Th are Natural Science scholarships at most of colleges and prizes in the ancillary medical subje Some of these are entrance scholarships; some m be gained by students already in residence, and wh suitable candidates are not forthcoming among st students the emoluments may be allotted to memb of other colleges. A valuable scholarship institu on behalf of Medicine is the Tancred Studentship Physic, tenable at Gonville and Caius College. T successful candidate must enter at the college wit a month or remove there if he be a member of a other college. Students are required to take degree of M.B. as soon as they are of suffici standing but may hold the Studentship for a furt three years. Thus a student elected previous admission to college can draw the emolument, annual value of which is about £90, for eight ye Full particulars can be obtained from Mr. E. Gurdon, 28, Lincoln's Inn-fields, London. Amo other scholarships and prizes may be mentioned Balfour Studentship, for research in Biology, of value of £200 a year for three years, open to the wh University; the Frank Smart Scholarship and Pri for Botany and Zoology, and the Shuttlewo Studentship for Zoology or Physiology tenable a at Gonville and Caius College. The one Univers Prize in Medicine, the Raymond Horton Smith Pr (value £19), is awarded to that candidate for the deg of M.D. who presents the best thesis for the deg during the academical year, provided that he has ta honours in a tripos examination.

An abstract of the Regulations and Schedules of range of the examinations in Chemistry, Physi Biology, Pharmacology, and General Pathology m be obtained upon sending a stamped directed envel to the Registrar, The Registry, Cambridge.

ADDENBROOKE'S HOSPITAL.—190 beds. Clini Lectures in Medicine and Surgery, in connexion w Cambridge University Medical School, are given this hospital twice a week during the academi year; and practical instruction in Medicine a Surgery is given in the wards and out-patien rooms by the physicians and surgeons daily duri the term time and vacations. The fee for pupils is 3 guineas a term, 9 guineas a year, 12 guin perpetual. Further information may be obtained fr Dr. Aldren Wright.

UNIVERSITY OF LONDON.

The University of London was established by Royal Charter in 1836 as an examining and degree-conferring body with affiliated colleges but no direct teaching functions. In 1900 it was reconstituted under the Act of Parliament, 1898, and became a teaching as well as an examining body. The External side of the work of the University needed no great amendments; the developments have been upon the Internal side. Many schools already existing became constituent colleges, including all the metropolitan medical schools.

Internal and External Students.—All the examinations of this University are open to men and women alike. Matriculated students of the University may be either internal or external. Internal students of the University are students who have matriculated in the University and who are pursuing a course of study approved by the University, either (*a*) under the direct control of the University or a committee appointed thereby; or (*b*) under one or more of the appointed or recognised teachers of the University. Centres for preliminary and intermediate medical studies have been established by the University at University and King's Colleges. Internal students must pursue their studies at one of the above centres, or at one of the medical schools connected with the University. These are St. Bartholomew's Hospital, Charing Cross Hospital, St. George's Hospital, Guy's Hospital, King's College Hospital, the London Hospital, St. Mary's Hospital, the Middlesex Hospital, St. Thomas's Hospital, University College Hospital, Westminster Hospital, and the London (Royal Free Hospital) School of Medicine for Women. Various schools and hospitals are also recognised as schools of the University in special departments, and students may pursue their studies at other approved universities and medical schools, presenting themselves for examination at the University.

Faculty of Medicine.—The Faculty of Medicine grants the joint degrees of M.B., B.S. (*Bachelor of Medicine and Surgery*), the higher separate degrees of M.D. (*Doctor of Medicine*) and M.S. (*Master of Surgery*), and the degree of B.D.S. (*Bachelor of Dental Surgery*); the two higher degrees being open only to candidates holding the M.B., B.S degrees of the University. The curriculum for the M.B., B.S. degrees is five and a half years from the time of matriculation, with certain exceptions which must be looked for in the official regulations of the University.

A. *Internal Students.*—For the Bachelor's degrees in Medicine and Surgery a student must normally, after registration as an internal student, have: (1) Attended prescribed courses of study for five and a half years in one or more schools of the University. (2) Passed the following examinations, under the conditions mentioned below: (*a*) The First Examination for Medical Degrees in Inorganic Chemistry, Physics, including Mechanics, and General Biology; (*b*) the Second Examination for Medical Degrees: Part I., Organic Chemistry; Part II., Anatomy, Physiology, and Pharmacology; (*c*) the Third Examination for Medical Degrees, or M.B., B.S. Examination in Medicine, Surgery, Obstetrics and Gynæcology, Pathology, Forensic Medicine, and Hygiene.

B. *External Students.*—For the Bachelor's degrees in Medicine and Surgery an external student must (1) have passed the Matriculation examination or have been exempted therefrom under Statute 116 not less than five and a half years previously; (2) have passed subsequent examinations similar to those required of an internal student; and (3) have been engaged in professional studies during the five and a half years subsequently to Matriculation and four and a half years subsequently to passing the First Examination for Medical Degrees at one or more of the medical institutions or schools recognised by this University for the purpose, one year at least of the four and a half years to have been spent in one or more recognised institutions or schools in the United Kingdom.

The First Examination for Medical Degrees (*Inorganic Chemistry, Physics, including Mechanics, and General Biology*) will take place twice in each year, commencing on the Monday following Dec. 7th and on the first Monday in July. It must be passed not less than nine months after matriculation.

The Second Examination for Medical Degrees (*Part I.*) *: Organic Chemistry.*—This examination will take place twice in each year, commencing on the Thursday following the second Monday in March and on the Thursday following the first Monday in July. No candidate will be admitted to this examination until he has completed the First Examination.

The Second Examination for Medical Degrees (*Part II.*) takes place twice in every year, commencing on the Tuesday following the third Monday in March and on the Tuesday following the first Monday in July. No candidate shall be admitted to the examination unless he has passed the First Examination for Medical Degrees at least 18 months previously, and has passed Part I. of the Second Examination for Medical Degrees.

The Third or M.B., B.S. Examination.—The M.B., B.S. examination takes place twice in each year, commencing on the second Monday in November and on the first Monday in May. No candidate will be admitted to this examination unless he has completed the Second Examination for Medical Degrees, together with a course of study summarised below, nor within three years from the date of passing the Second Examination, Part II., in Anatomy and Physiology. The course of study comprises introductory course in (1) Clinical Medicine; (2) Clinical Surgery; and (3) Clinical Pathology; (4) Experience as Clinical Clerk; (5) Clinical Medicine; (6) (*a*) Fevers, (*b*) Children's Diseases, (*c*) Venereal Diseases, (*d*) Mental Diseases (at a recognised Asylum), (*e*) Dermatology, (*f*) Vaccination, (*g*) Materia Medica and Pharmacy; (7) Experience as a Surgical Dresser; (8) Clinical Surgery; (9) Ophthalmology; (10) Oto-Rhino-Laryngology; (11) (*a*) Operative Surgery, (*b*) Applied Anatomy, (*c*) Administration of Anæsthetics, (*d*) Dental Surgery, (*e*) Orthopædic Surgery; (*f*) Mechano-therapeutics; (12) Obstetrics and Gynæcology; (13) Lying-in Hospital; (14) The conduct of at least 20 Labours; (15) Antenatal Clinic; (16) Experience as a Clinical Clerk in Gynæcological Work; (17) General Pathology, Morbid Anatomy, Bacteriology, and Chemical Pathology; (18) Work in the Post-Mortem Room; (19) Clinical Laboratory; (20) Forensic Medicine; (21) Hygiene. He must have attended the Medical and Surgical Practice of a recognised hospital for two years, and have held the posts of clinical clerk and surgical dresser for periods of six months each. Candidates will be examined in Medicine, Pathology, Forensic Medicine and Hygiene, Surgery, Obstetrics and Gynæcology. The subjects may be divided into two groups—namely: (1) Medicine, Pathology, Forensic Medicine, and Hygiene; and (2) Surgery, Obstetrics, and Gynæcology. These groups may be taken either separately or together. Bachelors of Medicine who graduated before May, 1904, may obtain the B.S. by passing the Surgical part of the M.B., B.S.

Doctor of Medicine.—The examination for this degree takes place twice in each year, commencing on the second Monday in December and on the first Monday in July. Candidates may present themselves for examination in one of the following branches—namely: (1) Medicine; (2) Pathology; (3) Psychological Medicine; (4) Midwifery and Diseases of Women; (5) State Medicine; and (6) Tropical Medicine. Any candidate for the degree of M.D. (except in branch 5) may transmit to the Registrar a thesis for approval and may be exempted from a part or from the whole of the written examination.

Master of Surgery.—The examination for the degree of Master of Surgery takes place twice in each year: (1) Surgery; (2) Dental Surgery; (3) Ophthalmo-

logy; (4) Laryngology, Otology, and Rhinology. A thesis may be submitted as for M.D.

Bachelor of Pharmacy.—The Senate has approved the institution of the Degree of Bachelor of Pharmacy, the course extending over three years.

Full details of the prescribed curricula can be obtained free on application to the Academic Registrar, University of London, South Kensington, S.W. 7.

MEDICAL SCHOOLS OF THE UNIVERSITY OF LONDON.[1]

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—The hospital contains 757 beds, of which 687 are for patients in the hospital at Smithfield and 70 at the Alexandra Hospital, Swanley. Special departments have been organised for Diseases of Women and Children, the Eye, Ear, Larynx, and Skin, as well as for Orthopædic and Dental Surgery, and for Electrotherapeutics and X Ray work. Whole-time Clinical Units under Professors of Medicine and Surgery have been established.

Ten house physicians and ten house surgeons are appointed annually, are provided with rooms and board, and receive £80 a year as salary. A resident midwifery assistant, an ophthalmic house surgeon, and a house surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and board and receive a salary of £80 a year. Three resident administrators of anæsthetics are appointed, the senior for one year at a salary of £150, and two juniors for six months with a salary at the rate of £80 per annum, with board and rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical in-patients and to the out-patients, and the dressers in the special departments are chosen from the students. A residential College is attached to the hospital.

There are quarters for the resident staff, casualty, medical, surgical, and special out-patient departments, casualty wards, dispensary, and clinical lecture theatre. There is a chemical laboratory attached to the College as well as a laboratory devoted to instruction in Public Health. A block is devoted to Pathology, and contains the post-mortem room as well as extensive laboratories for bacteriology, clinical pathology, and pathological chemistry. *The Medical College Buildings* include three large lecture theatres, a large dissecting room, laboratories for chemistry, biology, morbid anatomy and histology, and public health, as well as a spacious library (containing 14,500 volumes), a well-appointed museum of anatomy, physiology, comparative anatomy, materia medica, botany, and pathological anatomy. The pathological museum is complete. A new block in Giltspur-street has recently been acquired and has been fitted up as lecture theatres and laboratories for physics, chemical physiology, experimental physiology, histology, and pharmacology.

Special Classes for the Primary and Final F.R.C.S. are held twice yearly. *Instruction in Preliminary Science* is given to University of London students in chemistry, biology, and physics throughout the year. Facilities for research work are afforded in the Clinical Units and Laboratories of pathological and other departments. *A Vacation Post-graduate Course*, adapted to general practitioners, is given annually.

Scholarships given in aid of Medical Study.—For five of the Scholarships and the Exhibition—namely, (*a*), (*b*), two Entrance Scholarships in Science of the respective values of £75 and £100; (*c*) Entrance Scholarship in Arts, £100; (*d*) Jeaffreson Exhibition, £50; and (*e*) Shuter Scholarship, £50—a full or University course at St. Bartholomew's Hospital is required. The awards of (*a*) and (*b*) are made after examination in selections from the subjects Chemistry, Physics, Zoology, Botany, Physiology, Anatomy, and Pathology; (*c*) and (*d*) are awarded after examination in Mathematics, Latin, Greek or French or German, a second language, Chemistry or Physics; (*e*) is awarded after competitive examination among Cambridge Graduates in Anatomy and Physiology. The more important of the other Scholarships and prizes are as follows:—Four Junior Scholarships—(*f*) No. 1, £30, Anatomy and Physiology; (*g*) No. 2, £20, Anatomy and Physiology; (*h*) No. 3, £25, Chemistry, Physics, and Biology; (*i*) No. 4, £20, Chemistry, Physics, and Biology; (*j*) Senior Scholarship, £50, Anatomy, Physiology, and Chemistry; the Kirkes Scholarship, £30 and medal, Clinical Medicine; (*l*) and (*m*) two Brackenbury Scholarships, £39 each, one in Medicine and one in Surgery; (*n*) Sir William Burrows Prize, 10 guineas, Pathology; (*o*) Skynner Prize, 13 guineas, Regional and Morbid Anatomy; (*p*) Matthews Duncan Medal and Prize, £20, Midwifery and Gynæcology; (*q*) Luther Holden Research Scholarship in Surgery, awarded by election, £10; (*r*) Lawrence Research Scholarship and Gold Medal in Pathology, awarded by election, £115; and (*s*) Baly Scholarship in Clinical Medicine, £50, awarded by examination.

The recreation ground of 10 acres is at Winchmore Hill for the use of the members of the Students' Union, which all students are expected to join. The Students' Union contains a large reading and smoking room, a committee and writing room, luncheon and dining hall, and a miniature rifle range.

Information may be obtained on application to the Dean of the Medical College: Dr. T. W. Shore. The Warden of the Residential College is Mr. R. M. Vick.

CHARING CROSS HOSPITAL.—The Hospital, to which the School is attached, contains 300 beds. There are special departments for Mental Diseases, Midwifery, Diseases of Women, of Children, of the Skin, Ear, Throat, Nose, and Teeth, for Orthopædic Cases, X Ray work, and for Electrical Treatment.

In the Medical School Demonstratorships and Assistant Demonstratorships are open to students of the School. Medical, Surgical, and Obstetric Registrars to the Hospital are appointed annually. Six House Physicians, six House Surgeons, and two Resident Obstetric Officers are appointed each year. Women students are admitted to the School and Hospital upon the same terms and conditions as men, and after qualification are eligible for resident Hospital appointments.

By an agreement with the University of London the School sends its Primary and Intermediate Students to receive their lectures and practical work at King's College, which is situated within four minutes' walk.

Final studies are taken in the school and hospital, where systematic lectures, demonstrations, and tutorial classes are arranged to cover all the subjects necessary for qualifying examinations. Departments are also available for other final subjects of Materia Medica and Operative Surgery.

An Institute of Pathology with a whole-time staff of scientific workers and fully equipped laboratories has been established. Students receive their training in Preventive Medicine, Pathology, Bacteriology, and Biochemistry here, and are encouraged to undertake research. Special facilities are available for post-graduate research and study.

The course in Ophthalmology is given in the Royal Westminster Ophthalmic Hospital adjoining. Special demonstrations are arranged for Post-graduates.

The Museum contains over 4000 specimens, including a notable collection of over 800 gynæcological specimens, the Cuthbert Lockyer Collection.

The social comfort and convenience of students are met by library, reading, and smoking-rooms, refreshment-room, in a Students' Club. The Club, which

[1] For Metropolitan Centres affording Post-Graduate Facilities see p. 439.

under the control of a committee of students, ovides needful athletic recreation, and includes also medical society.

Further information may be obtained on application the Dean, Dr. W. J. Fenton, Medical School, aring Cross Hospital, London, W.C.

ST. GEORGE'S HOSPITAL.—This hospital has a service 436 beds, of which 180 are allotted to surgical, 150 medical cases, and 100 are at the Convalescent ospital at Wimbledon. There are all the usual ecial clinical departments. One ward is set apart r Diseases Peculiar to Women, and there is a aternity Ward of 11 beds. Children's beds are aced in the women's wards. There are two hthalmic wards.

Twelve house physicians, 12 house surgeons, and casualty officers are appointed annually. Special tention is directed to the following paid appointents, among others, which are open to students ter they have held house office :—Resident Assistant ysician and Resident Assistant Surgeon, at £350 r annum each ; Medical Officer to the Atkinsonorley Convalescent Hospital, at £300 per annum ; edical Registrarship at £200 per annum , Surgical gistrarship at £200 ; Assistant Curatorship of the useum at £100 ; Obstetric Assistantship (Resident) £50 ; the post of Resident Anæsthetist at £100 ; the sts (2) of Junior Anæsthetists. each at £30.

Entrance Scholarships and Endowed Prizes of a tal value of £700 are awarded annually ; a detailed t is placed below. The entire teaching and laboraries are now devoted to purely clinical subjects, and rangements have been made with the authorities of ing's College for students who enter the first, second, third year of the curriculum as students of St. orge's to carry out the necessary courses of instruc-n at that College. Students then complete their urse, without payment of any entrance fee, in a hool entirely devoted to clinical work.

Scholarships and Prizes.—At this school five trance scholarships are given, the money value and e subjects of examination being as follows : (*a*) and) two William Brown Exhibitions, £120 and £80 spectively ; (*c*) and (*d*) two University Entrance holarships, 90 guineas and £70 respectively ; (*e*) evitt-Pendlebury Scholarship, £50, Anatomy and ysiology, except in the case of (*c*), subject of amination for which is General Pathology.

This year, in addition to these Scholarships, khibitions, each of the value of £40 and up to x in number, will be awarded to candidates of proved merit in the Entrance Scholarships Examiation. The others are as follows : (*f*) Allingham holarship in Surgery for Students qualified not more an two years, £85 ; (*g*) and (*h*) two Brackenbury izes, one in Medicine and one in Surgery, £33 each, en to students of not more than five years' standg ; (*i*) H. C. Johnson Memorial Prize, £19, Practical natomy ; (*j*) Pollock Prize, £23, Physiology, Physiogical Chemistry, and Histology ; (*k*) Clarke Prize, ; (*l*) Thompson Medal, £9, Clinical Reports ; *m*) Brodie Prize, £8, Clinical Reports ; (*n*) Webb ize, open to perpetual pupils, £34, Bacteriology ;) Sir Francis Laking Memorial Prize, £65, open to udents having registrable qualifications.

The St. George's Hospital Club, with smoking- and ncheon-rooms, is on the hospital premises, and an hletic ground at Wimbledon, is an amalgamation of e Hunterian Society, the *Gazette*, and the Rugby otball, cricket, lawn tennis, boxing, rifle, and golf ubs. Students have the advantage of a library of edical and scientific books which is kept up to date.

Further information may be obtained from the ean of the Medical School, Dr. A. Feiling.

GUY'S HOSPITAL.—This hospital contains 616 beds. he whole of the medical school has been rebuilt ring the last 27 years. It provides ample accomodation, with modern equipment, for all the noninical subjects of the medical curriculum.

House physicians, house surgeons, out-patient officers and assistant house surgeons, obstetric residents, house surgeons in the departments of ophthalmology and genito-urinary diseases, house physician in the department for diseases of children, clinical assistants, clerks to anæsthetists, surgeons' dressers, clerks to medical units, post-mortem clerks, extern obstetric dressers, and dressers and clerks in the special departments are appointed from among the students according to merit.

The following special departments are attached to the hospital : Departments of ophthalmology, laryngology, gynæcology, diseases of children, diseases of the nervous system, dermatology, otology, actinotherapeutics, anæsthetics, dentistry, orthopædics, vaccine, tuberculosis, genito-urinary and venereal diseases, Salomon's Welfare Centre (for Maternity and Children).

There is a Venereal Clinic, in accordance with the Scheme of the Local Government Board and London County Council. Lectures and clinical instruction are given, to which Medical Students and Practitioners are admitted without fee.

Scholarships. — Six entrance scholarships are awarded annually as follows :—(*a*) one War Memorial scholarship, of the value of £200, to be awarded alternately in Arts and Science (next award, July, 1928, in Arts ; (*b*) one Open Arts Scholar of £100 for students under 19 years of age ; candidates may offer themselves in either of the following groups : (1) English and any two of the following—viz., Latin, Greek, or Mathematics ; (2) English and any two of the following—viz., French, German, and Mathematics ; (*c*) one Open Junior Science scholarship for students under 20 years, £100 ; subjects, any two of the following : Inorganic Chemistry, Physics, and Biology, and Mathematics ; (*d*) a confined Junior Science scholarship of the value of £100 is offered for competition, annually in July, to candidates who have attended the Preliminary Science Classes at this School ; (*e*) two open Science scholarships : (1) a War Memorial scholarship of the value of £100, awarded annually in September ; (2) an open scholarship of the value of £80, awarded annually in September, for students who have completed the curriculum for, or passed the examinations in, Anatomy and Physiology for a medical degree in any University of the British Empire, and who, during the nine months immediately preceding the Scholarship examination, have not entered as students in any Metropolitan Medical School other than Guy's ; subjects, any two of the following : Anatomy, Physiology, Organic Chemistry, Pharmacology, General Pathology.

Within the grounds of the hospital are situated the residential college, with accommodation for 35 students, the students' club, with reading, smoking, luncheon, and dining-rooms, a fives court, and swimming bath. The athletic ground and club house is situated at Honor Oak Park, and can be reached in 20 minutes from the hospital.

Further information can be obtained from the Dean of the Medical School, Prof. T. B. Johnston.

UNIVERSITY OF LONDON : KING'S COLLEGE.—The Medical Faculty at this College deals with Preliminary and Intermediate subjects, and instruction in these subjects is given in the College laboratories by university professors and their assistants to students entering the College directly and also to students of the following four hospital schools which prepare only for the final examinations—viz., King's College Hospital, Westminster Hospital, St. George's Hospital, and Charing Cross Hospital. The Faculty is open to both men and women.

Scholarships.—(*a*) Two Warneford Entrance Scholarships of £30 each for four years. Examination in April, subjects selected from Divinity, Classics, Science. (*b*) Sambrooke Scholarship of £30 for three years. Examination in April, subjects selected from Classics, Science. (*c*) Worsley Scholarships : £100 in five annual instalments of £20. (*d*) Rabbeth Scholar-

ships of £30 and £15 for best work in first year. (*e*) Second Year Scholarship of £20 tenable for one year. (*f*) Daniell Scholarship of £40 for one year. Awarded on University Honours Examination. (*g*) The Layton and the Berridge Research Studentships of £150 per annum each.

For prospectus and further information application should be made to the Dean of the Medical Faculty, King's College, Strand, W.C. 2.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL.—The final subjects in the curriculum are taught at the Medical School of King's College Hospital, which is situated at Denmark Hill, S.E. 5.

The hospital has 400 beds, and provision will ultimately be made for 600. There are special departments for Bacteriology, Children, Clinical Pathology, Dermatology, Gynæcology and Obstetrics, Laryngology, Massage, Neurology, Odontology, Ophthalmology, Orthopædics, Otology, Physical Treatment, Psychological Medicine, Radiology, Rhinology, and Urology, each in charge of a specialist and his staff. Clinics are also held in applied pharmacology, cardiology, and medical chemistry.

The appointments open to students are those of clinical assistant to the special departments; medical, surgical, obstetric, and pathological tutorships; resident casualty officers, house physicians and house surgeons; resident anæsthetist; resident radiologist; bacteriologist; clinical pathologist; pathological, medical, surgical, and obstetric registrarships. Sixteen resident medical and surgical officers are appointed half-yearly.

Scholarships and Prizes.—(*a*) Warneford Scholarships, (*b*) Sambrooke Scholarship, (*c*) Rabbeth Scholarship, £20; (*d*) Medical Entrance Scholarships, £50 (Anatomy and Physiology), and £50 (Pathology and Pharmacology) open to students who (1) propose to take a degree at any British University, and have passed their University examination in Biology, Chemistry, and Physics, and who (2) will become students at King's College Hospital from date of entering upon Scholarship; (*e*) A Medical Entrance Scholarship in Science, value £50, tenable for five years, successful candidates to study at King's College and King's College Hospital; (*f*) Three Medical Scholarships, £40 for fifth-year students, £20 for third-year students, and £20 for second-year students; (*g*) Three Sambrooke Registrarships, open to matriculated students who have filled certain appointments in hospital; (*h*) Carter Prize, £15, Botany; (*i*) Tanner Prize, £10, Obstetrics and Diseases of Women; (*j*) Todd Prize, £4 4*s*. and medal, Clinical Medicine; (*k*) Two Burney Yeo Entrance Scholarships, £80 each, open to students of Oxford and Cambridge on the nomination of the Regius Professors; (*l*) two Raymond Gooch Scholarships, £120 each, open to students of British Universities on certain conditions; (*m*) an Epsom College Scholarship, value £50 at least, offered annually to a student of Epsom College who has taken the first part of the courses for Medical Degrees at the Universities of Oxford, Cambridge, or London. The Warneford and Sambrooke Scholars are required to take the subjects of the preliminary and Intermediate examinations at King's College, and the final subjects at King's College Hospital.

Dental School.—When the Hospital was built accommodation was provided for a Dental Department. This Department, fully equipped, is now in use, together with additional rooms for Dental Metallurgy, by the Dental School, which was opened in November, 1923, under the direction of Mr. A. Livingston, M.B., Ch.B., Mast. Dent. Surg. A full course is given in coöperation with King's College, and includes arrangements for students who desire to avail themselves of the special provisions of the Dentists Act.

The King's College Hospital Clubs and Societies Union consists of the Listerian and Musical Societies, the Students' Common Rooms, and the vario athletic and sports clubs. The athletic ground, ov six acres in extent, is on Dog Kennel Hill, about t minutes' walk from the hospital. There are al "Tennis Courts in the grounds of the Hospital a of "The Platanes"—a hall of residence for studen belonging to the hospital.

The Calendar of the School will be sent on applic tion to either of the following: Dr. H. Willough Lyle, Dean; Mr. S. C. Ranner, Secretary of t Medical School, King's College Hospital, Denma Hill, S.E. 5.

LONDON HOSPITAL.—The hospital, with its Medic College and Dental School, is situated in Mile En road, and contains 849 beds. There are speci departments for diseases of the Eye, Ear, Nose a Throat, Skin, Teeth, and Pediatric, Orthopæd Venereal, Radiological, Electro- and Physico-ther peutical and Inoculation Departments.

A Clinical Unit in Medicine, under the charge a whole-time director, provides for the more elabora methods of diagnosis and treatment, and takes leading part in the initiation and coördination medical research. The director has an assista director, two assistants, and two house physicians.

To each medical and surgical firm throughout t hospital there is attached a First Assistant, who responsible for instructing the clerks or dressers the firm in elementary medicine and surgery, a who assists the honorary members of the firm the preparation of their demonstrations. In t department of Obstetrics and Gynæcology there a two assistants and two resident accoucheurs. Speci courses of lectures and demonstrations are arrang in Medicine and Surgery and their ancillary subject Opportunities for research are provided under t supervision of the staff.

Owing to the large number of patients more appoin ments are open to students before and after qualific tion than at any other hospital. Holders of reside appointments have free board. Special classes a held for the examinations of the University of Londo for the Fellowship of the Royal College of Surgeon for the Membership of the Royal College of Physician and for other higher examinations. Special entries f medical and surgical practice can be made.

Scholarships and Prizes.—The following is a list the Scholarships and Prizes:—Price Scholarship £10 and one Entrance Scholarship of £50, subjects of Fir Medical Examination at the University of Londo Epsom College Scholarship, free education, subjec of First Medical Examination as above; Pri Scholarship, open to students of Oxford a Cambridge Universities, (1) £100, Pathology; (2) £7 Human Anatomy and Physiology; Buxton Prize, £4 subjects of Anatomy and Physiology; three Priz for Clinical Work, £20 each, Medicine, Surgery, a Obstetrics and Gynæcology; Sutton Prize, £2 Pathology; Duckworth Nelson Prize, biennial, £1 Practical Medicine, and Surgery; Letheby Prizes (£25, Chemistry and Chemical Pathology; eig Dressers' Prizes, amounting to £40, zeal, efficienc and knowledge of Elementary Clinical and Min Surgery; Hutchinson Prize, triennial, £60, Clinic Surgery; Treves Prize, £15, Clinical Surgery; tw Practical Anatomy Prizes, £6 and £4 respectivel Andrew Clark Prize, £14, Clinical Medicine and Path logy; T. A. Ross Proc. Acc. Prize, £10 10*s*., Clinic Medicine and Pathology; James Anderson Priz (4), £20, Elementary Clinical Medicine; Arnc Thompson Prize, £15, Diseases of Children; K. E. Payne Prize, Research Scholarship, £20, Patholog and Liddle Prize, triennial, £120.

Medical Research Funds.—Funds to the value of ov £90,000 permit of financial assistance being given students and graduates engaged in Medical Researc

Two Residential Hostels are provided for studen The recent additions to the hospital and colle buildings include the Dunn Clinical Laboratori The Bearsted Clinical Theatre, the Bernhard Bar

athological Institute, and a hostel for 40 resident edical officers. The Union Athletic Ground, 13 acres, within easy reach of the hospital.

Dean: Professor William Wright, London Hospital edical College, E. 1.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—The ospital and Medical School are situated close to addington station (G.W.R.) having on one side a oor district of 500.000 persons, and on the other side ie residential districts of Kensington and Bayswater. he hospital contains 288 beds and extensions in rogress will raise this number to 334 and provide vo new operating theatres. By a scheme of affiliaon, for teaching purposes, of certain neighbouring ospitals, the teaching facilities extend over 1000 eds. The Medical School provides complete courses f instruction, and students can join at once on assing a Preliminary Examination in Arts. Terms egin in October, January, and April.

Clinical Units in Medicine and Surgery were estabshed in 1920. Lying-in beds have recently been dded, and, in addition to this, arrangements have een made by which all students take out a short ourse of instruction in Practical Midwifery at Queen harlotte's Hospital without additional fee.

Students specially interested in Pathology and acteriology have singular advantages at St. Mary's. he institute comprises seven special departments, ie whole being under the personal direction of Sir lmroth Wright, F.R.S. Research Scholarships of 200 each are awarded annually to students working the departments of the institute; and research eds have been instituted. Clerkships in Pathology, acteriology, and Chemical Pathology, lasting for a eriod of three months, are open to students of the fth year, and enable them to carry out the Pathogical and Bacteriological investigations of the ards, and learn the necessary technique under ipervision. Seventy-two of these posts are available nnually. Numerous appointments are open to ewly-qualified members of the Medical School, ncluding ten salaried posts with salaries varying om £200 to £750 per annum.

Entrance Scholarships.—Two Entrance Scholarips of the value of £210 each are awarded annually, y nomination in July, the Geraldine Harmsworth cholarship, £200, and one or more University Scholarips of £200 are awarded in July.

The Athletic ground (10 acres) is situated at Vembley and can be reached in 20 minutes by a onstant service of trains. A large pavilion has ecently been added.

For further information apply to the Dean of the edical School.

MIDDLESEX HOSPITAL.—The hospital contains over 50 beds, with special wards for Cancer, Maternity nd Gynæcological and Ophthalmological cases, and or Diseases of Children. Other special departments nclude those for Diseases of the Eye, Ear, Nose and hroat, and Skin; Nervous diseases, Orthopædic cases, Diseases of the Rectum and Venereal Diseases. There also an Electro-Therapeutic department. The Cancer harity, containing 92 beds and Special Investigation aboratories, offers unrivalled opportunities for the udy of Cancer, both in its clinical and pathological spects. In the Electro-Therapeutic Department, udents obtain instruction in the Treatment of Lupus nd Cancer by the X ray method of treatment.

The Medical School, which includes the Blandutton Institute of Pathology and the Cancer Research aboratories is fully equipped for the theoretical and ractical teaching of all the subjects of the medical urriculum, and for the Diplomas in Public Health, for hich two courses are held yearly, commencing in pril and October. Ample laboratory and classoom accommodation is provided. The teaching aff includes 6 Professors, 32 recognised Teachers, Demonstrators, 4 tutors. The Bland-Sutton Institute of Pathology is completely equipped for routine hospital investigations, teaching and research work, and contains a new lecture theatre and large pathological, bacteriological, biochemical, and clinical laboratories, also smaller laboratories for individual research work. A well-equipped Anatomical and Pathological Museum and Reference Library offer every facility.

Other features of interest are: the institution of a course in Medical Radiology and Electrology, under the direction of the "Joel" Professor of Physics; D.P.H. course, under the direction of Dr. Charles Porter, M.O.H., St. Marylebone. A primary F.R.C.S. class is held, and special classes to prepare students for the Intermediate Examinations of the Universities.

All appointments are made without fee of any kind, and the following are appointed at intervals annually: six house physicians, eight house surgeons, two obstetric and gynæcological house surgeons, two casualty medical officers, two casualty surgical officers, two resident anæsthetists, and two resident officers to the special departments. The medical and surgical casualty officers are appointed twice a year. Nine registrars are appointed annually. Non-resident qualified clinical assistants are appointed to assist in the various out-patient departments. Clinical clerks and surgical dressers are also appointed in every department.

Scholarships and Prizes.—Two Entrance Scholarships, value £100 each, and two University Scholarships, value £90 and £60, are awarded annually in September. The successful candidates are required to become general students of the school. A Freer Lucas Scholarship is awarded annually on the nomination of the Headmaster of Epsom College. There are also two Broderip Scholarships, value £60 and £40 respectively; the Lyell Gold Medal and Scholarship, value £55 5*s.*; the John Murray Medal and Scholarship, value £25 (awarded every third year); the Freeman Scholarship, value £30; the Hetley Clinical Prize, value £25; the Leopold Hudson Prize, value 11 guineas; and the Second Year's Exhibition, value 10 guineas. There are also numerous class prizes.

The Amalgamated Students' Club includes the following: Medical Society, Common Room Society, Musical Society, cricket club, football clubs, athletic club, rowing club, chess club, lawn tennis club, and hockey club. There are a restaurant and gymnasium in the school buildings, and large athletic grounds at N. Wembley, with new pavilion.

For further particulars apply to the Dean or the Secretary of the Medical School.

ST. THOMAS'S HOSPITAL.—This Hospital contains 644 beds. There are special departments for the treatment of women, children, diseases of the eye, ear, nose and throat, skin, teeth, and for orthopædics. Nervous and mental diseases are treated in special departments. An electro-cardiograph has been installed for the investigation of diseases of the heart. The Tuberculosis Department forms a part of the Lambeth scheme for treatment of patients and for instruction. The Venereal Department has been established as part of the London County Council scheme. Departments for Radiology, Electro-therapy, Phototherapy, Massage and Remedial Physical Exercises are also special features. A speech clinic has been inaugurated in connexion with the Children's Department. Exceptional facilities are offered in the hospital laboratories for the study of General Pathology, Clinical Pathology, Chemical Pathology, and of Treatment by Serums and Vaccines. Surgical operations take place in the main theatres every day, except Saturdays, at 2 P.M. Clinical teaching in the wards, out-patients' and special departments, is available every day of the week. Clinical lectures are delivered every Wednesday during the sessions. A Clinical Unit in Medicine has been established.

All appointments in the hospital are open to students without extra fee. Clinical clerks and

dressers for in- and out-patients are selected from students who have completed their third years' work. Every student acts as clerk in the post-mortem room and in one of the pathological laboratories, takes his turn on maternity duty under proper supervision in the maternity ward and district, thus obviating any necessity for seeking instruction elsewhere. Students are instructed in the administration of anæsthetics by the hospital anæsthetists.

The arrangements are made to meet the requirements of all the Examining Bodies. Special classes are held for the examinations at the University of London and for the First and Final Fellowship Examinations of the Royal College of Surgeons of England. Tutorial classes in all subjects precede the various examinations. The hospital is easily accessible from all parts.

Appointments.—A Resident Assistant Physician and a Resident Assistant Surgeon, salary £225 each per annum, and a Resident Anæsthetist, salary £200 per annum, are appointed annually. Two Hospital Registrars, Medical and Surgical, at an annual salary of £250 each are appointed yearly. The tenure of these offices may be renewed for a term not exceeding two years. A Pathological Registrar to the Department of Obstetrics and Gynæcology (at an annual salary of £250), an Ophthalmic Registrar (at an annual salary of £50), and an Orthopædic Registrar (unpaid) are appointed yearly. Two Senior Resident Casualty Officers (Medical and Surgical) are appointed yearly. Eight Resident Casualty Officers and Anæsthetists are appointed every six months. Seven House Physicians (including two Obstetric House Physicians, and one House Physician to the Department of Diseases of Children), nine House Surgeons (including two Ophthalmic House Surgeons, one Orthopædic House Surgeon, and two House Surgeons to the Ear, Nose and Throat Department) are appointed every six months. Clinical Assistants in the Special Departments are appointed every three months, and hold office for six months if recommended for re-election. There are three Assistants in the Department of Pathology; the Senior receives £600 a year, and the two Juniors £450 each.

Scholarships and Prizes.—At this school there are five Entrance Scholarships—namely, two in Arts, equivalent to the tuition fees for the first year of study; two in Natural Science, of the value of £150 and £60 respectively; and the University Scholarship of £100 in any two of the following: Anatomy, Physiology, Pathology, Chemistry. The value of all entrance scholarships must be taken out in tuition fees. The money value and subjects of examination of the remainder are as follows: (*a*) William Tite Scholarship for second-year students, £25; (*b*) and (*c*) Musgrove Scholarship or (alternately) Peacock Scholarship, each for third-year students and tenable for two years, £35 each; (*d*) Mead Medal, Medicine, Pathology and Hygiene; (*e*) Wainwright Prize, Medicine; (*f*) Toller Prize, Medicine; (*g*) Cheselden Medal, Surgery and Anatomy; (*h*) Clutton Memorial Medal in Clinical Surgery, biennial; (*i*) Beaney Scholarship, £50, biennially, Surgery and Surgical Pathology; (*j*) Solly Medal and Prize, biennial, Reports of Cases; (*k*) Sutton Sams Prize, biennial, Report of Cases; (*l*) Bristowe Medal, Pathology and Morbid Anatomy; (*m*) Hadden Prize, Pathology and Morbid Anatomy; (*n*) Grainger Testimonial Prize, £31 10*s*., Anatomy and Physiology; (*o*) Louis Jenner Research Scholarship, tenable for two years, £60 annually, Pathology; (*p*) School Council Research Scholarship, £250 per annum, tenable for two years; (*q*) John and Temple Research Fellowship, tenable for two years, £450, Children.

St. Thomas's House, the New Students' Club recently opened, comprises spacious dining-, smoking-, and reading-rooms, and accommodation for some 60 resident students. There is no occasion for students to leave the hospital premises during working hours.

Further information may be obtained from the Dean of the Medical School.

UNIVERSITY OF LONDON, UNIVERSITY COLLEGE.—University College has been constituted a University centre for the teaching of medical science. The College Faculty of Medical Sciences comprises the Departments of Physics, Chemistry, Botany and Zoology (the Preliminary Medical Sciences); also the Departments of Anatomy, Histology, Physiology, Biochemistry, and Pharmacology (the Intermediate Medical Sciences), and the Department of Hygiene and Public Health. Research work is undertaken in all departments. The completion of the Institute of Medical Sciences, which the generosity of the Rockefeller Foundation made possible, provides exceptional facilities for research and post-graduate study in anatomy, physiology, and pharmacology. In particular might be specified the opportunities for investigation in human and comparative embryology and neurology, in histology, radiology, anthropology, biochemistry, and experimental physiology and experimental embryology. Arrangements exist for the close correlation of work in the Institute with University College Hospital and Medical School.

Scholarships and Prizes.—The first three items of the present list require a complete intermediate course at University College. The money value and subjects at examinations are as follows: (*a*) The Buckney Scholarship, 160 guineas; (*b*) and (*c*) two Entrance Exhibitions, 55 guineas each, Chemistry, Physics, Botany, and Zoology; (*d*) Cluff Memorial Prize, £1 biennially, Anatomy, Physiology, Pharmacology, and Chemistry; (*e*) Schafer Prize in Physiology, £5 triennially; (*f*) Sharpey Physiological Scholarship, £115, Biological Sciences; (*g*) Morris Bursary for sons of deceased professional men, by nomination, tenable for two years, £16 a year; and (*h*) five Gold and five Silver Medals awarded annually in various departments.

Women students are admitted.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.—The final subjects in the curriculum are taught at the Medical School of the hospital, which has 500 beds including 60 in the new obstetric hospital. The course of instruction is suitable for the examinations at the Universities of Oxford, Cambridge, Durham, and other British Universities, and for the medical education required by the Examining Board in England and the Society of Apothecaries. Clinical Units in Medicine, Surgery, and Obstetrics and Gynæcology are now in operation. The whole-time Directors of the Units are concerned with the organisation of the teaching generally, but the honorary staff are responsible for the largest share of the teaching in the wards and Out-patient Department of the hospital. The department of otology, rhinology, and laryngology (the Royal Ear Hospital) has been provided with a separate building in Hunter-street, adjacent to the obstetric hospital. It contains 38 beds, including eight private wards for patients of limited means. The hospital is equipped with all modern appliances for investigation. The new buildings of the Obstetric Hospital of 60 beds (rendered possible by the Rockefeller Benefaction), the new Residents' House (with accommodation for 30 residents and students), the extension to the Nurses' Home, and new research laboratories for the Medical School are now finished and in full occupation.

Those who are desirous of carrying out original research in Pathology, including Morbid Anatomy, Bacteriology, Experimental Pathology, and Chemical Pathology, are admitted to work in the laboratories of the school by the Professor of Pathology and under certain conditions can receive grants from the Charles Graham Medical Research Fund. A special course of instruction is given in conjunction with University College for preparation for the examinations for Diplomas in Public Health of the various universities and examining bodies. In the Dental School in Great Portland-street, formerly known as the National Dental Hospital, there is afforded the opportunity for attending lectures and practical instruction in diseases of the mouth and teeth.

Appointments.—Clerkships and dresserships to the physicians, surgeons, anæsthetist, and pathologist are

lotted amongst the students of the hospital. aternity students are appointed each month and side in the Students' House connected with the edical School and Hospital. Fourteen house ysicians, six house surgeons, ten obstetric assistants, vo house surgeons to the Royal Ear Hospital (of the tal number of resident officers not more than three ay be held by women students at any one time) are lected annually by examination from among the nior students who have a medical qualification. ll house officers reside free in the hospital. In ldition to these posts there are certain special ppointments which are vacant from time to time nd are filled by senior students of the hospital: esident Medical Officer, Surgical Registrar, Medical egistrar, Obstetric Registrar, Harker-Smith Cancer egistrar, Ophthalmic Registrar, Registrar to the oyal Ear Hospital, Casualty Medical Officer and a asualty Surgical Officer, Assistants in Ear and hroat, Skin and Venereal Diseases Departments, nd House Anæsthetist.

Scholarships and Prizes.—At this School the first vo Scholarships (*a*) and (*b*) entitle the holder to a mplete course at University College and University ollege Hospital Medical School; the second two (*c*) nd (*d*) entitle to a final course at the Medical School. he money value and subjects of examination are as llows:—(*a*) Entrance Scholarship, Bucknill, 135 ineas, Chemistry, Physics, Botany, and Zoology;) Epsom Free Medical Scholarship, subjects of reliminary Scientific Examination and Nomination y Epsom College; (*c*) and (*d*) two Goldsmid Entrance xhibitions 112 guineas each, Anatomy or Physiology, General Pathology; (*e*) Graham Scholarship in athology, £300 per annum for two years, awarded y the Senate of the University of London; (*f*) tkinson Morley Scholarship, tenable for three years, 45 per annum, Surgery; (*g*) Atchison Scholarship, enable for two years, £55 per annum, General roficiency in Medical Studies; (*h*) Magrath Clinical cholarship, about £150, Clinical Cases; (*i*) Percival lleyn Scholarship, about £75, Surgery; (*j*) Filliter xhibition, £30, Pathology; (*k*) Erichsen Prize, £10 10*s*., ractical Surgery; (*l*) two Senior and two Junior ellowes Clinical Medals for Clinical Medicine; (*m*) two iston Gold Medals for Clinical Surgery; (*n*) Alexander ruce Gold Medal for Pathology and Surgery; and) Tuke Silver and Bronze Medals for Pathology.) Radcliffe Crocker Travelling Scholarship for ermatology. (*q*) Leslie Pearce Gould Travelling cholarship for Surgery.

The *Museum of Pathological Anatomy* is open for tudy daily, and microscopic sections of most of the pecimens have been prepared and are available for he use of students on application to the Curator. The Anatomical Museum of the University of London, University College, is open to all students of University ollege Hospital and Medical School on the recom- nendation of the School Committee. The Medical ibrary, open daily to every student of the School, ontains about 20,000 works on medical subjects, ncluding all the current text-books and works of eference required for study or research.

The Medical Society of University College Hospital Medical School exists for the dual purpose (1) of romoting the study of medical and surgical science, nd (2) of promoting social intercourse among its embers. All male students of the Medical School are equired to become members. Meetings are held once fortnight for the purpose of discussing subjects onnected with the study of medicine. In its social spect the society includes various athletic clubs and uperintends the gymnasium and squash racquet ourt in the Medical School, and the Athletic Ground t Perivale.

University College Hall, Ealing, is recognised by he authorities as a residential hostel. The Students' louse in University-street contains large and com- ortable rooms. The Maternity Students occupy hem on payment of a moderate charge.

Full information can be obtained from the Dean of the School.

WESTMINSTER HOSPITAL.—The Hospital contains 236 beds. By a scheme for the concentration of the teaching of the preliminary and intermediate subjects of the curriculum, which has the support of the London University, an arrangement has been made by the Westminster School for the teaching of these subjects at King's College. Students, however, may join the Westminster Medical School as formerly and may compete for Entrance Scholarships as heretofore. There are separate departments for Diseases of the Eye, Skin, Teeth, Ear, Nose, and Throat, for Orthopædic practice, for Diseases of Women, for Diseases of Children, for Radiography, for Venereal Diseases, and for Massage, Electrical and Light Treatment. The Anatomical, Pathological, and Materia Medica Museums are open to all students of the school.

The usual registrarships and house appointments are open to male and female students.

Scholarships and Prizes.—The following Entrance Scholarships are offered for competition: Winter Session: Two Scholarships in Anatomy and Physiology, £70 each. Summer Session: Two Scholarships in Anatomy and Physiology, £70 each. A certain number of Scholarships have been allotted to Universities of England, Wales, and the Colonies, and to Public Schools. These Scholarships are awarded entirely on the nomination of the principal of the university or school. During the period of study the following prizes may be competed for: Sturges Prize in Clinical Medicine, about £6, Reports on Cases; Clinical Surgery Prize, £5, Reports on Cases; Chadwick Prize, £21 in books or instruments—Medicine and Surgery, including Pathology and Applied Anatomy and Physiology; Frederic Bird Medal and Prize, open to Fourth-year Students, £14 in medal and books or instruments—Midwifery, Diseases of Women, Medicine, Pathology, Forensic Medicine and Bacteriology, and Public Health and Toxicology; Abrahams Prize in Clinical Pathology, 5 guineas, a Paper and Tests in Practical Work; Alfred Hughes Memorial Prize, open to Second-year Students, about £5 in books or instruments—Anatomy; Huxley Memorial Prize, 3 guineas in books or cash, open to Second-year Students—Physiology; Carter Gold Medal and Prize for Botany, open to Students of not more than three years' attendance, gold medal and books of the joint value of £15; Jelf Medal awarded to Third-year Students; Second-year Scholarship £20, Elementary Anatomy, Physiology, Histology, and Organic Chemistry; Daniell Scholarship, £40, Chemistry; Rabbeth Scholarships open to First-year Students, one of £30 and one of £10; Class Examinations in the Preliminary Scientific Course.

The Athletic Grounds are situated in Tooting and are reached in 20 minutes from the hospital.

Inquiries should be addressed to the Dean of the Medical School.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN, 8, Hunter-street, W.C.—The Royal Free Hospital contains 240 beds. The Hospital also has large Casualty and Out-patient Departments, and Departments for Special Diseases. A new and specially equipped block contains the Obstetrical and Gynæcological Unit, which controls 68 beds. A Children's Department, including 18 cots, an Orthopædic Department, and a Light Department have recently been added to the Hospital. Maternity Districts are attached to the Unit operating in the Gray's Inn-road and Essex-road areas. A new Maternity Hostel has been acquired at 434, Essex-road. Students also attend the in-patient and out-patient practice of the Elizabeth Garrett Anderson Hospital, Cancer Hospital, Hospital for Sick Children, Great Ormond-street, National Hospital for Paralysed and Epileptic, South London Hospital, and Royal London Ophthalmic Hospital.

A Clinical Unit in Obstetrics has been established. Courses are arranged for the Primary Fellowship Examination of the College of Surgeons; also for dental students in conjunction with the Royal London Dental Hospital, Leicester-square.

The School buildings have been entirely rebuilt in recent years, and there are spacious, well-equipped laboratories, which afford every facility for efficiency of teaching and practical work in all departments.

There are residential chambers at 8, Hunter-street, 25, Gordon-square, 16, Brunswick-square, 5, Mecklenburgh-square, and 36, Tavistock-square, and the Warden can be consulted on the subject of other residences for students. The Students' Union arranges the social, athletic, and other clubs and societies. The School sports ground, consisting of 7½ acres of freehold land, is situated at Sudbury (easily reached from Euston Station).

Students after qualification can hold the posts of house physicians, house surgeons, obstetric assistants, clinical assistants, assistant anæsthetist, medical, gynæcological, and surgical registrars, and assistant pathologist; and at the Medical School the posts of demonstrators in the departments of Anatomy, Physiology, Pharmacology, Biology, Chemistry, and Physics. Many other resident posts in London and elsewhere are also open to them.

Scholarships and Prizes.—(*a*) Isabel Thorne Scholarship, £30. (*b*) St. Dunstan's Medical Exhibition, £60 a year, tenable for three or five years. (*c*) Mrs. George M. Smith Scholarship, £50 a year, tenable for three or five years. (*d*) Bostock Scholarship, tenable for two or four years, £90 (*e*) Mabel Sharman-Crawford Scholarship, tenable for four years, £20 a year. (*f*) Sir Owen Roberts Scholarship, £75 a year for four years. (*g*) Mabel Webb Research Scholarship, tenable for one year and renewable, £30, Physiology, Chemistry, or Pathology. (*h*) Fanny Butler Scholarship, tenable for four years; next award in July, 1931, £16. (*i*) John Byron Bursary, tenable for two years, for students already in the School requiring assistance for the prosecution of their medical studies; application to the Secretary by March 31st next, £20. (*k*) Helen Prideaux Prize and Julia Ann H. Cock Prize, awarded alternately every year to a student who has become qualified during the two years immediately preceding the award, and to be spent in assisting the holder to further study, £60 each. (*l*) Dr. Edith Pechey Phipson Post-graduate Scholarship of the value of £100, awarded annually in June. It is open to all medical women, preferably coming from India, or going to work in India, for assistance in Post-graduate study. (*m*) Sarah Holborn Scholarship, value £20 a year for three or five years, awarded every alternate year; next award in 1929. (*n*) Dr. Margaret Todd Scholarship, tenable for four years, £37 10*s*. a year, awarded in alternate years; next award in July, 1929. (*o*) Lieutenant Edmund Lewis and Lieutenant Alan Lewis Memorial Scholarship, tenable for four years, awarded every four years; next award in July, 1928. (*p*) Alfred Langton Scholarships, tenable two years, one awarded annually, £50 a year. (*q*) School Jubilee Bursary, tenable for three years, £50 a year. (*r*) Flora Murray Bursary, awarded every year to a fifth-year student, £50. The Dorothy Chick Gift, £20, is awarded annually for efficiency in Practical Midwifery. Two Richardson-Kuhlmann Prizes are given each year, value £12, for proficiency in Clinical Obstetrics, value £8, for proficiency in senior subjects respectively. Two Evans Prizes of £2 2*s*. and £1 1*s*. are given each year on the results of the class examination in Midwifery. The Evans Prize for Operative Midwifery, value £5 5*s*.; the Dr. Helen Webb Prize for Children's Diseases, £5 5*s*.; the Mary Swann Prize in Gynæcology, £5 5*s*.; the Edward Hanson Prize in Physiology, £2 10*s*.; and the Edith Pechey Phipson Prize in Pharmacology, value £3 3*s*., are awarded annually.

Inquiries may be addressed to the Warden and Secretary of the Medical School.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (University of London).—The new Departments of Bacteriology and Immunology under Prof. Topley, and of Epidemiology and Vital Statistics under Prof. Greenwood, will open with advanced courses of study on Oct. 4th next, the Bacteriology course (covering the new Diploma) at 6, Gordon square, W.C., and the Epidemiology course at the National Institute for Medical Research at Hampstead. The existing Departments of the School dealing with the courses of study for Tropical Medicine and Hygiene will continue for the present in the building occupied by the Hospital for Tropical Diseases at Endsleigh-gardens. There are two such courses in the year, each lasting 20 weeks, inclusive of examinations. The dates for the commencement of each course are Oct. 3rd, 1927, and March 12th, 1928, respectively. The course covers the work required for the D.T.M. and H. (England) and part of that required for the M.D. in Tropical Medicine of the University of London. For facilities for clinical and pathological study the School is indebted to the Seamen's Hospital Society, who, prior to August 1st, 1924, were responsible for the London School of Tropical Medicine. Research studentships and scholarships are available, and full particulars with regard to these and the courses of study generally may be obtained from the Secretary of the School, 23, Endsleigh-gardens, Euston-road, W.C.

UNIVERSITY OF DURHAM.

Nine degrees, two Diplomas, and one Licence are conferred—viz., the degrees of Bachelor of Medicine, Bachelor of Surgery, Doctor of Medicine, Master of Surgery, Doctor of Surgery, Bachelor of Hygiene, Doctor of Hygiene, Bachelor of Dental Surgery and Master of Dental Surgery, the Diploma in Public Health, Diploma in Psychiatry, and the Licence in Dental Surgery.

For the degrees of *Bachelor of Medicine* and *Bachelor of Surgery* there are four professional examinations. The subjects of the First Examination are—Elementary Biology and Organic Chemistry. The subjects of the Second Examination are—Anatomy and Physiology. The subjects of the Third Examination are—Materia Medica, Pharmacology, general principles of Therapeutics and Pharmacy, Medical Jurisprudence, Public Health, and Pathology and Bacteriology. The subjects of the Fourth Examination are—Medicine, Clinical Medicine, Therapeutics, Surgery, Clinical Surgery, Operative Surgery, Midwifery and Gynæcology, Psychological Medicine, and Diseases of the Skin, of the Throat, Nose, and Ear, and of Children, and Ophthalmology. It is required that at least one of the five years of professional education shall be spent at the University College of Medicine, Newcastle-upon-Tyne.

For the degrees of *Doctor of Medicine* and *Master of Surgery* a candidate must not be less than 24 years of age. He must also have obtained the degrees of Bachelor of Medicine and Surgery of the University of Durham, and must have been engaged for at least two years subsequently to the date of admission to these degrees in research work, or in attendance on the practice of a recognised hospital, or in the naval or military services, or in medical or surgical practice. The candidate for the M.D. degree may present an essay or undergo a special clinical examination in the Theory and Practice of Medicine. The subjects of examination for the M.S. are:—Principles and Practice of Surgery, Surgical Pathology, Surgical Anatomy, Surgical Operations, Clinical Surgery.

Doctor of Medicine (without residence).—The University of Durham has instituted a special examination whereby the degree of Doctor of Medicine may be obtained without residence. Candidates must not be under 40 years of age and must have been in active practice for 15 years as registered medical practitioners. They must also produce certificates of moral character from three registered members of the medical profession. The fee is 50 guineas (including the degree fee), of which 20 guineas is retained if the candidate fails to satisfy the examiners.

Doctor of Surgery.—The University of Durham grants the Degree of Doctor of Surgery. Candidates

or this degree must be registered medical practitioners, and not less than 24 years of age. They must devote three years, subsequently to obtaining registrable qualification, to the study of Surgery and ancillary subjects. One at least of the three years must be spent in the University. The candidate must submit to the Professor of Surgery the course of study he proposes to follow, and this course must be approved by the Board of the Faculty of Medicine. One year shall be devoted mainly to work in the departments of Anatomy, Physiology, Pathology, and Bacteriology, and the candidate must submit evidence of having so worked. Not less than six months of another year must be spent as resident surgeon in a recognised teaching hospital, and the rest of the year in the study of surgery in a recognised medical centre. Not less than six months of one of the three years must be spent in surgical study abroad.

Candidates for any of the above degrees, diplomas, or licence must give at least 28 days' notice to the Registrar, College of Medicine, Newcastle-upon-Tyne. In the case of the M.D. (essay) examination candidates must send in their essays before April 1st.

Scholarships and Prizes.—The following are awarded:—University of Durham Entrance Scholarship, £25 a year for four years; Pears' Entrance Scholarship, £40 a year for three years (awarded every third year); Province of Durham Masonic (Entrance) Scholarship, £60; Heath Scholarship for Surgery, £200, available every second year; Rutherford Morison Surgical Scholarship, £180, available every third year.

The following Scholarships are tenable for one year, namely:—Tulloch Scholarship for Elementary Biology and Organic Chemistry, £20; Dickinson Scholarship for Medicine, Surgery, Midwifery, and Pathology; Gold Medal and £20; Charlton Scholarship for Medicine, £25; Gibb Scholarship for Pathology, £28; Duke Armstrong Scholarship for Comparative Pathology, £25; Stephen Scott Scholarship for Surgery, £40; Philipson Scholarships for highest marks in final M.B., B.S. Examinations, two of £48 each; Goyder Memorial Scholarship for Clinical Medicine and Clinical Surgery, interest on £325; Gibson Prize for Midwifery and Diseases of Women and Children, £10; Turnbull Prize and Silver Medal for Surface Anatomy; and Outterson Wood Prize for Psychological Medicine, £10; Sewell Memorial Prize and Silver Medal for Clinical Pathology.

For further information apply to the Registrar of the College.

COLLEGE OF MEDICINE, Newcastle-upon-Tyne.—The clinical courses are taken at the Royal Victoria Infirmary. In it adequate accommodation is provided for the study of the various special subjects, in addition to the routine clinical work, while midwifery is studied at the Princess Mary Maternity Hospital. The bacteriological laboratory is adjacent to Armstrong College.

Students' Union Buildings have been erected and furnished at a cost of over £54,000, and are now in daily use.

NEWCASTLE-UPON-TYNE ROYAL VICTORIA INFIRMARY.—The Infirmary has 572 beds. Clinical lectures are delivered by the Physicians and Surgeons weekly and ward demonstrations are given daily. Tutorial classes are held by the Assistant Physicians and Assistant Surgeons, and demonstrations are given in the several out-patient departments daily. Pathological demonstrations are given by the Pathologist daily or as opportunity occurs, and in the new buildings nothing has been spared in perfecting scientific equipment. In addition to medical and surgical in-patient and out-patient departments the following special departments are fully equipped for teaching students: Ophthalmic, Throat, Nose, and Ear, Skin, Gynæcological, and Electrical. The hospital building contains the following laboratories: 1. Special Pathological Laboratory, attached to the post-mortem rooms. 2. Bacteriological Laboratory, in which all clinical bacteriological investigations are carried out with a view to treatment by vaccines and serums. 3. There is in addition a Clinical Laboratory attached to each ward and to the out-patient department. There are five operating theatres in use in the hospital. The winter session of 1927 opens on Oct. 4th and the summer session of 1928 on April 11th.

Applications for detailed information should be made to the Dean, Dr. Horsley Drummond, at the hospital.

Practical Midwifery is studied at the Princess Mary Maternity Hospital, a new building, excellently equipped, with 90 beds. Instruction is given in Psychological Medicine at the City of Newcastle Mental Hospital. A special course of instruction is given in the City Hospital for Infectious Diseases by the City Officer of Health. Ophthalmology is taught at the Northumberland, Durham, and Newcastle Infirmary for Diseases of the Eye.

Post-Graduate Instruction.—1. General courses in Clinical Medicine, Surgery, and Pathology at the Royal Victoria Infirmary, meeting once weekly for ten weeks. One course will be held from October to December and one from April to June. 2. Special courses of clinical instruction, meeting once weekly for ten weeks, in the following subjects: Gynæcology; Diseases of the Eye; Diseases of the Throat, Nose, and Ear; Diseases of the Skin; Venereal Diseases; Neurology; Diseases of Children; Electro-therapeutics and Radiology; special courses in Midwifery will be held at the Princess Mary Maternity Hospital. 3. An intensive course of 14 days' duration in the early part of the Summer Vacation. 4. In addition to the regular post-graduate courses practitioners may attend the ordinary medical and surgical practice of the Royal Victoria Infirmary for specified periods.

UNIVERSITY OF BIRMINGHAM.

The University of Birmingham grants the degrees of M.B., Ch.B., M.D., Ch.M., and Ph.D. (for Research Study), and also a degree and a diploma in Public Health. The course for the Bachelors' degrees extends over five years from the date of commencement of professional study. As a rule the first four of these years must be spent in the University, but the Senate has power of recognising attendance at another University as part of the attendance qualifying for these degrees and of recognising examinations passed at such other Universities as exempting from the examinations in Biology and Organic Chemistry. In the case of such students at least three years must be spent in attendance upon classes at the University. The fifth year may be spent at any other medical school recognised by the University.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—The student must have passed the Matriculation Examination of the Joint Board or an examination accepted in lieu thereof, and a recognised Pre-Medical Examination in Chemistry and Physics. All communications respecting the Matriculation Examination, and examinations accepted in lieu thereof, must be sent to the Secretary, Joint Matriculation Board, 315, Oxford-road, Manchester. First Examination.—Part I., Elementary Biology and Organic Chemistry; Part II., Anatomy and Physiology. Second Examination.—General Pathology and Bacteriology, Materia Medica, and Pharmacy. Third Examinations (at the end of the fourth year).—Forensic Medicine, Toxicology, Public Health, and Therapeutics. Two years' hospital work must have been accomplished. Final Examination.—Medicine, Surgery, Midwifery, Diseases of Women, Mental Diseases, and Ophthalmology. Attendance at a general hospital for a year after the passing of the fourth examination will be required, also attendance at a fever hospital three months, maternity hospital three months, and mental hospital three months. Vaccination instruction must be taken and courses of Ophthalmology, Venereal and Skin Diseases, and Diseases of Ear, Nose, and Throat, Medical and Surgical Anatomy, and Operative Surgery.

Distinctions may be awarded in the subjects (severally) of the First, Second, Third, and Final, and Honours in the Final Examination.

Degrees of Doctor of Medicine and Master of Surgery. At the end of one year from the date of having passed the final M.B., Ch.B. examination the candidate will be eligible to present himself for the higher degrees of either Doctor of Medicine or Master of Surgery or both. Candidates have to present a thesis on some subject embraced in the medical curriculum, and pass a general examination in Principles and Practice of Medicine for the M.D., and one in Principles and Practice of Surgery, including operations on the cadaver, for the Ch.M., or, at the discretion of the examiners, in a special branch of Medicine or Surgery respectively. A thesis of exceptional merit may exempt from any part of these examinations, in which Honours may be awarded.

Degree of Ph.D.—The Degree of Doctor of Philosophy is conferred upon candidates who possess a medical degree of a British, Colonial, or other university approved of by the Senate of the University, and who have been engaged, to the satisfaction of the Medical Faculty, in advanced study and research for a period of not less than two years, either in a laboratory of the University or in one or more of the hospitals associated with the University. After the first year candidates may carry on research elsewhere, under approved conditions, and on completing the course present a thesis and submit themselves for oral and possibly written examination.

Scholarships and Prizes.—The following are awarded:—(*a*) Myers Travelling Studentship of £300, tenable for one year, offered in alternate years, awarded by vote of committee to M.B., Ch.B. candidates, tenable at some University or Hospital not in Great Britain or Ireland (available for year 1927–28); (*b*) two Ingleby Scholarships of £10 each awarded to the candidate at Final Examination obtaining highest "first-class" marks in the subjects of Midwifery and Diseases of Women; (*c*) Sydenham Scholarship of £42, tenable for three years, award of Council to orphan sons of medical practitioners; (*d*) Sands Cox Scholarship of £21 per annum during two years, awarded to the candidate, not being more than 19 years of age, taking the highest marks at the Higher School Certificate Examination of the Joint Matriculation Board; (*e*) Dental Scholarship of £37 10*s*., Open Competitive Examination in subjects learned during apprenticeship; (*f*), (*g*), (*h*), and (*i*) Four Queen's Scholarships of £10 10*s*. each. In the Second and Fourth Examinations the Scholarship is awarded respectively to the student taking the first place and obtaining not less than 75 per cent. marks. In the Third Examination the Scholarship is awarded to the student obtaining the highest, but not less than 75 per cent., marks in Pathology and Bacteriology, provided that such student passes at the same examination in the subjects of Materia Medica and Practical Pharmacy. In the Final Examination the Scholarship is awarded to the candidate taking the first place in the examination—that is, obtaining the greatest aggregate number of marks—provided that in each of the subjects of Medicine, Surgery, and Midwifery he gains not less than 60 per cent. of the total available marks; (*j*) George Henry Marshall Scholarship of £10, awarded annually, for the encouragement of Research Work in Ophthalmology; and (*k*) Russell Memorial Prize, a prize of books, value about £2, awarded annually to the student who, not being of more than six years' standing as a student of the School of Medicine of the University, shall pass the best examination in the subject of Nervous Diseases. The "Arthur Foxwell Memorial Medal" (Gold Medal for Medicine) and the "Sampson Gamgee Memorial Medal" (Gold Medal for Surgery) are awarded annually to the best candidates passing Final M.B., Ch.B. Examination in June in Medicine and Surgery respectively, provided that not less than 60 per cent. of marks is obtained (paper, oral, and clinical). The University Clinical Board awards Gold and Silver Medals on examinations in Medicine, Surgery, and Midwifery, respectively, in fourth and fifth years, open to all students.

Clinical Instruction.—The medical students of the University receive their clinical instruction by attending the amalgamated practice of the General Hospital and the Queen's Hospital under the direction of the University Clinical Board. Appointments are open to students varying from £40 to £200 a year.

BIRMINGHAM GENERAL HOSPITAL.—370 beds. Special wards for Children, Gynæcological, Ear and Throat, Venereal, Maternity, and Septic cases; special beds for Eye and Skin cases. Laboratories for Bacteriology and Morbid Histology. Separate rooms adjoin the medical and surgical wards for clinical pathology. Five operating theatres (one for out-patients), all designed and fitted on modern lines. In addition to clinical teaching given in the wards and out-patient department by the honorary staff, medical and surgical tutorial classes are held for senior and junior students. Clinical instruction in all the special departments, which include those for Radium, Electrotherapy, Electrocardiographic investigation, and Venereal Diseases. Post-graduate classes in every branch of medicine and surgery. The Jaffray Branch Hospital contains 56 beds.

QUEEN'S HOSPITAL.—224 beds.—Similar arrangements for clinical teaching are made here, and the material also is excellent. Ward and tutorial classes and post-graduate courses are regularly conducted by the staff, there are daily clinics in the out-patient department, while teaching duties are definitely assigned to the house physicians and house surgeons. There are also special departments for gynæcology and ophthalmology, dentistry, radiography, pathology, bacteriology, biochemistry, massage, electricity, whirlpool baths, and electrocardiograph.

BIRMINGHAM AND MIDLAND EYE HOSPITAL, Church-street, Birmingham.—115 beds. Students attending for a period of three months will be granted certificates which will qualify for the University and Conjoint Board examinations. Post-graduate courses are available on various subjects, when a sufficient number of graduates are present. A limited number of Non-Resident Clinical Assistants posts are available to qualified practitioners, particulars of which can be had on application to the General Superintendent.

Post-Graduate Instruction.—A "William Witherin Lectureship" has been established. A course (of courses) of lectures is given annually for post-graduates on subjects chosen from year to year. In 1928 a course on Industrial Disease will be given by Sir Thomas Legge. The Ingleby Lectures on some subject in connexion with Diseases of Women and Children are given annually by specially appointed lecturers. Post-graduate Courses of Clinical Demonstrations for General Practitioners are arranged annually (April to July) at the Birmingham General, Queen's, and Children's Hospitals.

UNIVERSITY OF LIVERPOOL.

The degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Doctor in Philosophy (Ph.D.), Master of Surgery (Ch.M.), Master of Hygiene (M.H.), and Master of Orthopædic Surgery (M.Ch.Orth.).

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for the degrees of Bachelor of Medicine and of Surgery must have attained the age of 22 years on the day of graduation. At least two of the five years of medical study must have been passed in the University, and one year at least must have been passed in the University subsequently to the date of passing the First Examination. The other three years may be passed at any college or medical school recognised for this purpose by the University. Candidates must pass three examinations entitled respectively the First Examination, the Second Examination, and the Final Examination. The subjects

e First Examination are: (1) Chemistry; (2) ysics; (3) Biology (Zoology and Botany). The bjects of the Second Examination are (*a*) (1) atomy; (2) Physiology (including Physiological emistry and Histology); and (*b*) (3) Elementary cteriology, (4) Clinical Chemistry, (5) General thology. Candidates may present themselves in or (*b*) separately. The subjects for the Final amination are: (*a*) (1) Special Pathology and rbid Anatomy; (2) Forensic Medicine and Toxi- ogy; (3) Public Health; (4) Pharmacology and neral Therapeutics; (*b*) (5) Obstetrics and Diseases Women; (6) Surgery, Systematic, Clinical, erative and Practical, including Ophthalmology; Medicine, Systematic and Clinical, including Thera- utics, Mental Diseases, and Diseases of Children. ndidates may present themselves in Parts (*a*) and separately, but candidates must have completed e fifth year of medical study before taking rt (*b*).

Degrees of Doctor of Medicine and Master of Surgery. candidate will be admitted to the degree of ctor of Medicine or Master of Surgery unless he s previously received the Degrees of Bachelor of edicine and Bachelor of Surgery, and at least two ars have elapsed since he passed the examinations those degrees, or, in the case of the degree of ctor, unless, having obtained substantially equiva- nt degrees in an approved University, he has sub- quently spent two years in the University or in the nical School in the performance of research or the nduct of systematic clinical observations. Candi- tes for the degree of Doctor of Medicine are required present a thesis together with, if desired, published ginal work relative to medical science, and unless e thesis is of special merit to submit to an examina- n in medicine, or to a special written or oral amination on subjects connected with the thesis.

The University also awards a *Diploma in Medical diology and Electrology*—Part I., Physics: Part II., diology and Electrology. The parts may be taken one examination or separately.

Scholarships, Fellowships, and Prizes.—The follow- g are awarded: (*a*) Robert Gee Entrance Scholar- ip (Men), annually, of £40, tenable for four ars; (*b*) Lyon Jones Scholarship, No. 1, of 1 per annum, tenable for two years, Com- titive Examination among Junior Students in rst M.B. Subjects; (*c*) Lyon Jones Scholar- p, No. 2, of £21, Competitive Examination on sults of Professional Examination in Anatomy, ysiology, Elementary Bacteriology, Clinical Chem- ry, and General Pathology; (*d*) Derby Exhibition £15, Competitive Examination among Fourth- Fifth-year Students in Clinical Subjects, and (*e*) nical School Exhibition of £15 annually for Fourth- Fifth-year students; (*f*) University Scholarship £50 for one year, awarded on results of the Final art A) Examination for the degrees; (*g*) Holt Fellow- ips, Physiology and Pathology, of £150 each, for one ar; (*h*) Gee Fellowship, Anatomy, of £100, for e year; (*i*) John Rankin Fellowships in Anatomy, o, each of the value of £120, tenable for two years; Johnston Colonial Fellowship, Biochemistry, £100, for one year; (*k*) John W. Garrett Inter- tional Fellowship, Bacteriology, of £100, for one ar; (*l*) Thelwall Thomas Fellowship, Surgical thology, of £150, for one year; (*m*) Ethel Boyce llowship in Gynæcological Pathology, of £100, for e year; (*n*) Mary Birrell Davies Memorial Fund holarship, of the value of £60, tenable for four years, ered for competition in alternate years; open only women students who will have attained the age 19 on the first day of October next following the ard; (*o*) Rankin Exhibition in Practical Anatomy, £25, for one year; (*p*) Lady Jones Research llowship in Orthopædic Surgery, £200; (*q*) Samuels emorial Scholarships, three at £20; numerous izes and medals.

The Medical School.—All the laboratories and class- oms are situated close together, communicating with e another, and are made up of four large blocks of buildings which form one side of the College quad- rangle. There are the Johnston Laboratories for Experimental Medicine and Biochemistry; the Medical School for Anatomy, Surgery, Toxicology, and Ophthalmology; and the Thompson-Yates Laboratories for Physiology and Pathology. A new building for Tropical Medicine has been opened. Medical research has also been endowed with several new laboratories in which students can pursue research work after graduation.

Clinical Studies.—The Clinical School of the University consists of four general hospitals—the ROYAL INFIRMARY, the DAVID LEWIS NORTHERN HOSPITAL, the ROYAL SOUTHERN HOSPITAL, and the STANLEY HOSPITAL; and of six special hospitals—the Eye and Ear Infirmary, the Hospital for Women (with the Samaritan Hospital), Liverpool Maternity Hospital, the Royal Liverpool Children's Hospital, St. Paul's Eye Hospital, and St. George's Hospital for Skin Diseases. These hospitals contain in all a total of about 1445 beds. The organisation of these hospitals to form one teaching institution provides the medical student and the medical practitioner with a field for clinical education and study which is unrivalled in extent in the United Kingdom. All the hospitals are within easy access of the University. There are a large number of appointments to house physicianships and surgeon- ships both at the general and special hospitals which are open to qualified students of the school.

Public Health Department.—This is located in a separate building, in which full courses of instruction are given to students for the Diplomas and Degrees of the University and of other Examining Boards.

Prospectuses and further information may be had on application to the Dean of the Faculty of Medicine, University of Liverpool.

VICTORIA UNIVERSITY OF MANCHESTER.

Four degrees in Medicine and Surgery are conferred by the University—viz., Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). A Diploma in Psychological Medicine, a Diploma in Public Health, and a Diploma in Bacteriology are awarded by examination to registered medical practitioners.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Before admission to the degree of M.B. or Ch.B. candidates are required to present certificates that they will have attained the age of 21 years on the day of graduation, and that they have pursued the courses of study required by the University Regulations during a period of not less than five and a half years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in the University subsequently to the date of passing the first M.B. Examination.

The First Examination: (1) Chemistry and Physics; (2) Biology. Candidates must have attended during at least one year courses both of lectures and of laboratory work in each of the above-named subjects. The Examination is divided into two parts: Part 1, Inorganic and Elementary Organic Chemistry and Physics; Part 2, Biology. The candidates sit for these parts separately. The Second Examination: (1) Anatomy and Histology; (2) Physiology, including Physiological Chemistry. The Third Examination: (1) Pharmacology and Materia Medica; (2) Pathology. The Final Examination: (1) Medicine, Systematic and Clinical (including Mental Diseases and Diseases of Children); (2) Surgery, Systematic, Clinical, and Practical; (3) Obstetrics and Gynæcology (including Clinical and Practical); (4) Forensic Medicine (including an Oral Examination); (5) Hygiene and Preventive Medicine. The Final Examination is divided into two parts: Part I., Forensic Medicine, Hygiene and Preventive Medicine; Part II., Medicine, Surgery, Obstetrics and Gynæcology (Systematic, Clinical, and Oral). Candidates for the Second Part must complete the sixth year of medical study.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously obtained the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. Candidates may elect either (1) to present an original dissertation; or (2) to undergo an examination. The dissertation must embody the results of personal observation or original research, either in some department of medicine or of some science directly relative to medicine. The examination, which will be written and practical, is in the Principles and Practice of Medicine, in Pathology, and in some other subject to be selected by the candidate.

Degree of Master of Surgery.—Candidates are not eligible for the degree of Master of Surgery unless they have previously obtained the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. The degree is conferred in the following branches: Surgery (Branch I.), Gynæcology (Branch II.), Ophthalmology (Branch III.), Laryngology, Otology, and Rhinology (Branch IV.).

Degrees of B.Sc. and M.Sc.—The ordinary degree of B.Sc. in the Schools of Anatomy and Physiology may be obtained by students in Medicine who in their third year of study for the degree of M.B., Ch.B. complete the additional courses in these subjects prescribed for this degree. Candidates for the Honours degree of B.Sc. in Anatomy or Physiology, who are students in Medicine, are required to attend courses in advanced Anatomy and Physiology for four terms after passing the Second Examination for the degrees of M.B., Ch.B. Graduates in science may proceed to the degree of M.Sc. by presentation of an approved thesis.

Scholarships, Fellowships, and Prizes.—The following are offered in connexion with medical study at the Victoria University:—Scholarships: Dreschfeld Entrance (triennial), £20; John Russell Medical Entrance, £45; Sam Gamble Entrance for Women; Graduate Entrance (fees up to 160 guineas); two Dauntesey Medical Junior, £50 each; Dauntesey Medical Senior, £50; Professor Tom Jones Exhibition in Anatomy, £25; Dickenson Trust Scholarships in Anatomy and Pathology; Platt Physiological, £90; Graduate Research Scholarship, £70; Dickenson Trust Travelling Scholarships in Medicine and Surgery; Ashby Memorial in Diseases of Children (triennial), £100; John Henry Agnew in Diseases of Children, £120. Fellowships: Leech Research, £70; Professor Tom Jones, Surgical, £105; Morrison Watson in Anatomy, £150; Delépine in Preventive Medicine (biennial), £300; Honorary Research Fellowships. Prizes: Sidney Renshaw in Physiology, £15; Turner Medical, £20; Dumville Surgical, £15; Knight Prize in Psychological Medicine, £50; Graduate Prizes, £5 each. There are many general entrance scholarships, in addition to those already mentioned, open for competition, the examinations for which are held in the month of May. Full particulars can be obtained from the Registrar.

The Medical School.—This school, largely extended in 1920, is provided with dissecting-rooms, X ray rooms, physiological laboratories, private laboratories, and work-rooms, besides lecture-rooms, museums, and general and departmental libraries. A special laboratory is equipped for experimental work on the central nervous system. In the pathological laboratories ample provision is made for the teaching of pathology and bacteriology and for the prosecution of original research. The Helen Swindells Laboratory is specially equipped for cancer research and investigation in general pathology. Ample facilities for investigation are provided in Anatomy, Physiology, and Materia Medica. In the public health department, which is lodged in a separate institute in York Place, near the Royal Infirmary, suitable laboratory accommodation is provided for the study of sanitary chemistry, physics, and practical bacteriology in the departments of chemistry and physics and in that of pathology.

Clinical Studies.—The clinical and practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary and St. Mary's Hospitals for Women and Children, a fever hospital, a lunatic asylum, and a convalescent home, and other special hospitals. Medical and Surgical Clinical Classes are conducted in the Infirmary and separate instruction is afforded in the elements of Medical and Surgical Physical Diagnosis, in Obstetric Medicine, Ophthalmic Surgery, and Pathological Anatomy by the different members of the staff of the Medical School and Infirmary.

Post-graduate Studies.—Post-graduate Courses in Medicine and Surgery have been arranged for during 1927–28 as follows, in addition to those usually held at the various hospitals: 1. Whole-time intensive courses in (*a*) Medicine and Surgery, and (*b*) Obstetrics and Gynæcology. 2. Whole-time advanced courses in Diseases of the Digestive System. 3. Part-time afternoon courses in (*a*) Tuberculosis, and (*b*) Diseases of the Ear, Throat and Nose. 4. Clinical Assistantships. Syllabuses and other information may be had on application to the Dean of the Medical School, Manchester University.

MANCHESTER ROYAL INFIRMARY.—The Manchester Royal Infirmary is built on the pavilion system, near the University, and has accommodation for 668 patients (including 54 beds at the Central Branch). The medical side consists of four units, each unit having a testing-room for the scientific investigation of morbid products and a class-room. The surgical beds are also arranged in five units, each unit having its own operation theatre, with anæsthetising, recovery, sterilising, testing and apparatus rooms, and its own class-room attached. All of these units are occupied. In the education block is a large lecture theatre and a museum. In the same building is housed the X ray department, which has nine separate X ray outfits for different purposes and in which one large room is put aside specially for X ray demonstrations and teaching purposes. A large massage school is also connected with the department.

Associated with the Infirmary are: (1) the Convalescent Hospital at Cheadle, containing 132 beds; (2) the Royal Lunatic Hospital at Cheadle, accommodating with its branches 430 patients; and (3) the Central Branch in the City, which has now accommodation for 54 patients. The Associated Hospitals thus contain 1230 beds and are under the same management. Women students are admitted on the same terms as men.

Two Entrance Scholarships in Medicine of the value of £160 each are offered annually by the Council of the Manchester University and the Medical Board of the Manchester Royal Infirmary for proficiency in Arts and Science subjects respectively. Other scholarships and prizes are mentioned in the College syllabus. Numerous annual appointments and junior appointments may be held by those who have attended the practice of the Infirmary.

ROYAL MANCHESTER CHILDREN'S HOSPITAL, Pendlebury, Gartside-street, Manchester, and Lytham St. Anne's.—The hospital contains 190 beds and is in the Convalescent Home, Lytham St. Anne's. The medical staff visit the hospital daily at 10 A.M. Clinical instruction is given by the medical staff at the Hospital and Dispensary. There is a new Massage and Electro-therapeutic Department. Four Clinical Assistants are appointed for periods of six months. In throwing open these appointments to qualified medical men and women the Board is actuated by the desire to aid those qualified medical men and women who wish to have opportunities for the further study of disease in children, or who wish to fit themselves for posts as Medical Officers to Children's Hospitals, to Child Welfare Centres, or for School Medical Officer appointments. There is an Orthopædic Department. Out-patients' day is on Tuesday at Gartside-street and a ward at Pendlebury is devoted to cases needing

erative treatment. Out-patients are seen daily at .M. at the Out-patient Department, Gartside-street, nchester. Secretary: Mr. W. M. Humphry.

MANCHESTER NORTHERN HOSPITAL FOR WOMEN D CHILDREN, Park-place, Cheetham Hill-road, nchester.—The hospital contains 73 beds. Out-ients are seen daily from 8.30 to 12 A.M.

UNIVERSITY OF LEEDS.

Four degrees in Medicine and Surgery are con-red—viz.: Bachelor of Medicine and Bachelor of rgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), ster of Surgery (Ch.M.), also Degrees and Diplomas Dental Surgery and Diplomas in Public Health l in Psychological Medicine.

Degrees of Bachelor of Medicine and Bachelor of rgery.—Candidates for these degrees are required present certificates showing that they will have ained the age of 21 years on the day of graduation, l have attended courses approved by the University ending over not less than five years, two of such rs at least having been passed in the University, of which must be subsequent to the date of ssing the First Examination. Candidates must also isfy the examiners in the several subjects of the owing examinations, entitled respectively: the triculation Examination, or such other examination may have been recognised by the Joint Matricula-n Board in its stead; the First Examination; the ond Examination; and the Final Examination. e First Examination consists of: Part I., Physics d Inorganic Chemistry; Part II., Zoology and tany. Candidates will be allowed to pass the two rts separately. The Second Examination consists : Part I., Organic Chemistry; Part II., Materia dica and Practical Pharmacy; Part III., Anatomy, ysiology, and Pharmacology. Candidates will be owed to pass any parts separately, but Part I. must passed before Parts II. or III. The Final Examina-n consists of: Part I., Pathology and Bacteriology; rt II., Medicine, Surgery, Obstetrics, Gynæcology, l Clinical Pathology; Part III., Forensic Medicine, blic Health, and Therapeutics. Part I. may be ken at the end of the second clinical year, and rts II. and III. may be taken at the end of the third nical year, but not before the completion of the h year of medical study. If taken separately rt II. must be passed before Part III.

Degree of Doctor of Medicine.—Candidates are not gible for the degree of Doctor of Medicine or ster of Surgery unless they have previously received e degrees of Bachelor of Medicine and Bachelor of rgery of the University (or of Victoria prior to cember, 1904) and at least one year has elapsed ce they passed the examination for those degrees. ndidates for the degree of Doctor of Medicine e required to present a dissertation and, if the sertation be accepted, may be required to pass an amination. The first term commences on Oct. 1st. ospectus can be obtained from the Academic b-Dean.

Post-graduate work.—Practitioners wishing to attend firmary practice during short periods, or post-aduate classes held by members of the clinical ff, may do so on application to the Clinical Sub-an, from whom particulars may be obtained.

Clinical Studies.—The clinical studies are pursued ainly at the Leeds General Infirmary, which has commodation for 630 in-patients, including 88 beds branch hospitals in the country. Clinical teaching kes place daily in the wards, and Clinical lectures are ven in Medicine and Surgery by the Physicians and rgeons. There are Medical, Surgical, Ophthalmic, ural, Electro-therapeutic, and Radiographic Depart-nts, in each of which special instruction is imparted students. Gynæcological and Children's Depart-nts, together with Laryngeal, Venereal, and Skin nics, are in operation, and there is a special ward cases of nutritional disorders of children. Several luable prizes are given at the end of each session. Numerous appointments at the Infirmary are annually open to students after qualification. Further particulars may be obtained from the General Manager.

In addition to work in the General Infirmary, clinical instruction in obstetrics is given in the Leeds Maternity Hospital and in mental and infectious diseases in the Wakefield (W.R.) Mental Hospital and Leeds City Fever Hospital respectively.

UNIVERSITY OF SHEFFIELD.

The Degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.). There is also a Diploma of Licentiate in Dental Surgery. The courses and degrees in the Faculty of Medicine are open to men and women alike. Candidates must matriculate in the University or pass such other examination as may be recognised for this purpose by the University and sanctioned by the Joint Matriculation Board, and must pass also the further examination in Chemistry and Physics.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—A candidate must have attained the age of 22 years on the day of graduation and have pursued the courses of study required by the University regulations during a period of not less than five years subsequently to the date of his matriculation and the passing of the further examination in Chemistry and Physics, three of such years at least having been passed in the University, one at least being subsequent to the passing of the First Examination. The subjects of the First Examination are Chemistry, Physics, and Biology. The Intermediate B.Sc. Examination in these subjects will, on payment of the required additional fee, be accepted instead of this examination. Candidates must, after matriculation and the passing of the further examination in Physics and Chemistry, and registration as medical students, have attended courses of instruction (lectures and laboratory work) in chemistry, physics, and biology for one year each. The Second Examination: The subjects are Anatomy and Physiology. Candidates must have completed the second year of professional study. The Third Examination: The subjects are Pathology, Pharmacology, Anatomy, and Physiology. Candidates must have completed the Lent Term of the fourth year of professional study. The Final Examination: The subjects of the examination are: Part I., Forensic Medicine and Public Health; Part II., Medicine (including Mental Diseases and Diseases of Children), Surgery, Obstetrics (including Gynæcology). Candidates for Part I. must have completed the Michaelmas Term of the fifth year of professional study; candidates for Part II. must have completed the fifth year of professional study.

Degree of Doctor of Medicine.—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, must present a thesis embodying observations in some subject approved by the professor of medicine, and must pass an examination in the Principles and Practice of Medicine.

Degree of Master of Surgery.—Candidates must have taken the M.B., Ch.B. at least one year previously, and must since have held for not less than six months a surgical appointment in a public hospital.

The subjects of examination are Systematic, Clinical, and Operative Surgery, Surgical Anatomy, Surgical Pathology, and Bacteriology.

Scholarships.—At this University, in addition to six Edgar Allen scholarships of £125 a year for three years, holders of which can take the courses in the Faculty of Medicine, there are 11 scholarships tenable in the Faculty of Medicine. Full particulars as to curriculum, scholarships, and prizes, may be had on application to the Registrar or to the Dean of the Medical Faculty.

The Medical School.—The Medical Department occupies the entire north wing of the University

quadrangle. The various athletic and other students' societies are under the management of the Union Representative Council, elected annually. There are large and comfortable common rooms both for men and women students, and two Students' Unions, one for men and one for women. A refectory is open daily at the University where students may obtain meals and refreshments at moderate prices. The University journal, *Floreamus*, edited by a committee of staff and students, is published each term. The University Halls, "Oakholme," Clarkehouse-road; "Tapton Cliffe," Fulwood-road, and "Endcliffe House," Endcliffe Vale-road, are recognised by the Senate as halls of residence for women students; full particulars may be obtained from the tutor for women students. Stephenson Hall is a hall of residence for men students; particulars may be obtained from the Warden.

Clinical Studies.—The University is within easy reach of the various hospitals with which it is connected for clinical purposes.

The Sheffield Royal Infirmary, 502 beds, provides all the opportunities of a large general hospital with special departments for Skin and Ear. The Sheffield Royal Hospital, 316 beds, has special out-patient departments for Diseases of the Throat, Ear, Skin, Orthopædics, and Mental Diseases. The two institutions are amalgamated for the purposes of clinical practice, medical, surgical, and special. There are special departments for the treatment of Diseases of the Eye, with wards assigned to them, at both hospitals, and excellent junior appointments. The Jessop Hospital for Diseases of Women, with 93 beds, has also a Maternity department, with about 900 in-patients per annum and about 250 out-patient cases attended. The Children's Hospital has 60 beds. Special courses on Fevers are held at the City Fever Hospitals (690 beds) and on Mental Diseases at the South Yorkshire Mental Hospital (1800 beds). Every facility is afforded in the various laboratories for the prosecution of advanced studies and research.

UNIVERSITY OF BRISTOL.

In the Faculty of Medicine there are the following degrees:—Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.). There are also the following diplomas: Diploma in Public Health (D.P.H.), Diploma in Dental Surgery (L.D.S.), and Diploma in Veterinary State Medicine.

All candidates for degrees in Medicine, Surgery, and Dentistry are required to pass an examination called the School Certificate Examination, or to pass such examination as may be regarded as equivalent by the Senate. All courses, degrees, and diplomas are open to men and women alike.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates shall be not less than 21 years of age and shall have pursued the courses prescribed by University Regulations during not less than five years after passing the first examination in Chemistry and Physics, of which three shall have been passed in the University, and two of these three subsequent to passing the second examination. All candidates for the degrees of M.B., Ch.B., are required to satisfy the examiners in the several subjects of three examinations. The First Examination: The subjects of examination are: Chemistry (Inorganic), Physics, and Biology, the courses pursued being those for the time being approved for the intermediate part of the B.Sc. curriculum. This part of the curriculum shall extend over one year. (Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the first examination and will be regarded as having completed one year of study.) The Second Examination: The subjects of examination are: Organic Chemistry and Elementary Anatomy (Part I.) and Advanced Anatomy and Physiology (Part II. Parts I. and II. may be passed separately or together. The Final Examination: The subjects of examination are: Materia Medica and Pharmacy, Pharmacology and Therapeutics, General Pathology, Morbid Anatomy, and Bacteriology (Part I.); Special Pathology, Forensic Medicine, Toxicology, and Public Health, Obstetrics (including Diseases of Women), Surgery (Systematic, Clinical, Practical, and Operative), Medicine (Systematic, Clinical, and Practical, including Mental Diseases) (Part II.). The subjects included in Part II. may be taken in two groups, viz., Group I., Surgery and Obstetrics; Group II., Medicine, Public Health, Special Pathology, Forensic Medicine, and Toxicology. Candidates may pass Parts I. and II. together, or separately, and the two groups of Part II. may be taken together or separately. Forensic Medicine and Toxicology may be taken with Part I., or with Group II. of Part II.

Degree of Doctor of Medicine.—Candidates shall be Bachelors of the University of not less than two years' standing as such and may elect either (1) to pass an examination in General Medicine, or (2) to pass an examination in State Medicine, or (3) to present a Dissertation. The candidate who elects to pass the examination in State Medicine must hold a diploma in Public Health of some University or College, and the candidate who elects to present a Dissertation may be examined in the subject thereof.

Degree of Master of Surgery.—Candidates shall be Bachelors of not less than two years as such, during which period they shall have attended the Surgical Practice of an institution approved for the purpose. They shall pass an examination in Surgical Anatomy, Pathology, and Bacteriology, and Operative, Clinical, and General Surgery, and present to the University a Dissertation on some subject of Surgery. The degree may be taken also in General Surgery, and a Special Subject—e.g., Oto-Rhino-Laryngology, Ophthalmology, and Gynæcology.

Clinical Studies.—The allied hospitals (BRISTOL ROYAL INFIRMARY and BRISTOL GENERAL HOSPITAL) have between them about 600 beds and extensive out-patient departments, special clinics for Diseases of Women and Children and those of the Eye, Throat and Ear, in addition to large and well-equipped departments for Dental work and large outdoor Maternity Departments.

At each of these institutions there are well-arranged pathological museums, post-mortem rooms, and laboratories for Morbid Anatomy. There are also laboratories for work in Clinical Pathology, Bacteriology, and Cytology, in which special instruction is given in these subjects. Departments are provided and well equipped for X ray work, both for diagnosis and treatment, the various forms of Electrical treatment, including High Frequency Currents, Electric Baths, Finsen Light treatment, and Massage.

The students of the school also attend the practice of the Royal Hospital for Sick Children and Women, containing 140 beds, and that of the Bristol Eye Hospital, with 40 beds. The total number of beds available for clinical instruction is therefore about 750.

There are numerous salaried junior appointments for residents who are graduates.

Scholarships and Prizes.—The following are awarded: The Ashworth Hallett Scholarship, value £45, open to women only; two Martin Memorial Pathological Scholarships of £10 each; the Tibbits Memorial Prize, value 9 guineas, for proficiency in practical surgery; the Committee's Gold and Silver Medals for fifth-year students for general proficiency; the Augustin Prichard Prize, value about 6 guineas, for proficiency in anatomy; the Henry Clark Prize, value 11 guineas, for proficiency in gynæcology; the Crosby Leonard Prize, value 7 guineas, for proficiency in surgery; the Suple Surgical Prize, a gold medal and 7 guineas; the Suple Medical Prize, a gold medal and 7 guineas; the Henry Marshall Prize, value £

dressers; the H. M. Clarke Scholarship, value for proficiency in surgery; the Sanders Scholar-, value £22 10*s*., for general proficiency; the ett-Roué Scholarship for proficiency in diseases he eye, ear, nose, and throat, value £14; Lady erfield Scholarship, value about 25 guineas; llis Siepman Prize, for proficiency in Diseases of dren, value £25.

ristol City Senior Scholarships and those offered he counties of Gloucestershire, Somerset, Wilts, Devon, are tenable in the University. Some of Fellowships awarded by the Colston Research ety for research in the University are allotted to Faculty of Medicine.

ost-graduate Study.—Qualified medical practi-ers may be appointed as clinical assistants for a od of one or more months. They may act as stants, if times permit, in more than one depart-t and in any of the hospitals during their period tudy. They will be entitled to the use of the cal laboratories and medical library, and have the t to attend in all departments, including opera-s, post-graduate and ordinary clinical demonstra-s, and post-mortem examinations. Demonstration ses with weekly lectures are held during May, , and July. All inquiries and applications for ission should be addressed to the Director of -graduate Studies (Clinical Section), Pathological artment, University of Bristol, who can be seen ny day by appointment.

urther information as to scholarships, curricula, fees can be obtained from the Dean of the Faculty edicine or the Registrar of the University.

UNIVERSITY OF WALES.

his University has, inter alia, the privilege of ting Degrees in Medicine, and Diplomas in Public lth and Tuberculous Diseases. Preliminary ses of study for the Degrees in Medicine may be ued at any of the constituent Colleges of the versity—viz., at Aberystwyth, Bangor, Cardiff, or nsea. The Welsh National School of Medicine ituated in Cardiff and is an integral part of University College of South Wales and mouthshire there.

niversity College of South Wales and Monmouth-e, Cardiff. Welsh National School of Medicine.—School is staffed on the Unit System, and its rses of Instruction are open to both men and nen students. Students can complete the whole heir curriculum in the School. The courses of uction qualify for the degrees in Medicine and gery of the University of Wales, and for the rees and Diplomas of other examining bodies. pital instruction is given at the Cardiff Royal rmary, at the City Lodge Hospital, and at other gnised institutions. The attention of students ut to matriculate is drawn to the entrance scholar-s offered for competition at the University College, iff, many of which may be held by medical ents. Full particulars of the examinations for e, which are held in April of each year, may be ined by application to the Registrar. Medical titioners wishing to prepare for the Diploma in lic Health or for the Tuberculous Diseases loma of the University of Wales can attend plete courses of instruction in the School. Pros-uses can be obtained on application to the Dean ne Faculty of Medicine, or to the Secretary, Welsh ional School of Medicine, Newport-road, Cardiff.

linical Instruction.—At the Cardiff Royal Infirmary nded 1837, 450 beds) there are out-patient artments for Dermatology, Diseases of Children, Dental Cases, and a Maternity Hospital. nsea General and Eye Hospital (316 beds). artments: Pathological Laboratory; Venereal ases Department; Ophthalmic; Ear, Nose and oat; Women; X Ray and Massage. Convalescent ne, 26 beds.

ENGLISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Under this heading we give the regulations for the examinations enjoined by the Conjoint Examining Board of the Royal Colleges of Physicians of London and Surgeons of England and of the Society of Apothecaries upon students desiring their respective diplomas of qualification. We do not give any list of schools recognised by these bodies as eligible to prepare students for their examinations beyond mentioning that all the schools which we have already described (under the heading of the Universities to which they are attached) are recognised as suitable places of instruction by the corporations granting medical diplomas. The courses of study at the principal colonial medical schools are also recognised as qualifying for the examinations of these corporations.

Students are required to pass a *Pre-Medical Examination* in Chemistry and Physics conducted by the Conjoint Examining Board before commencing the five years curriculum of professional study or some other examination recognised by the Board—namely, the examination in Chemistry and Physics for the degree in Medicine of any University recognised by the Board; a Pre-Medical Examination conducted by any of the Qualifying Bodies whose Degrees or Diplomas are registrable on the Medical Register; the Higher School Certificates of Oxford and Cambridge Universities, and the Oxford and Cambridge Schools Examination Board; the Higher Certificates of London, Bristol, Durham Universities, the Joint Matriculation Board of the Northern Universities, and the Central Welsh Board Higher Certificate. A candidate must enter for Chemistry and Physics together, and he will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other subject. He will be admitted to the examination on producing evidence of having passed the required Preliminary Examination in General Education and of having received instruction during 180 hours in Chemistry and 120 hours in Physics to the satisfaction of his teachers. These courses may be commenced or attended before the required Preliminary Examination in General Education is passed. The examination is partly written, partly oral, and partly practical. A candidate rejected in one or both subjects of the examination will not be admitted to re-examination until after the lapse of a period of not less than three months, and he must produce evidence of further instruction in the subject or subjects of failure. The fee for the examination is £3 3*s*., for re-examination in Chemistry £2 2*s*., and for re-examination in Physics £1 1*s*.

There are two Professional examinations called the *First* and *Final Examinations*. The courses of study for these examinations may be commenced before the Pre-Medical examination in Chemistry and Physics or some equivalent examination has been passed, provided that three terms of study are completed after the examination has been passed.

The subjects of the First Professional Examination are: Section I. (*a*) Anatomy, including Histology and Embryology. (*b*) Physiology, including Biochemistry. Section II. Pharmacology, Practical Pharmacy, and Materia Medica. A candidate must have attended at a recognised Medical School courses of instruction in Anatomy, including Embryology, during five terms, during which he must have dissected the whole body, courses of instruction in Physiology, including General Biology, Biochemistry and Biophysics during five terms, courses of instruction in Pharmacology, Practical Pharmacy, and Materia Medica. A candidate may present himself

for the two Sections together or separately, but he must take parts (*a*) and (*b*) of Section I. together until he has passed in one or both parts, but a candidate will not be allowed to pass in one part unless he obtains at the same time at least half the number of marks required to pass in the other part.

Section II. of the examination may be passed at any time before the candidate enters for the Final Professional Examination. The fee for the First Professional Examination is £10 10*s*., for re-examination after rejection in Section I. £6 6*s*., for re-examination after rejection in either part of Section I. £3 3*s*., for re-examination after rejection in Section II. £3 3*s*. A candidate who produces satisfactory evidence of having passed an examination in the subjects of Section I. or of either part of Section I. and of Section II. in the examination for the degree in Medicine conducted at a University recognised by the Board will be exempted from further examination in such subjects.

Final Professional Examination.—The subjects of the Final Professional Examination are: Section I. Pathology (including Morbid Anatomy, Morbid Histology, and Clinical Pathology), and Bacteriology. Section II. Part I. Medicine, including Medical Anatomy, Forensic Medicine and Public Health. Part II. Surgery, including Surgical Anatomy and the use of Surgical Appliances. Part III. Midwifery and Gynæcology. The examination is partly written, partly practical, partly clinical, and partly oral. A candidate may take Sections I. and II. and the three parts of Section II. of the Final Examination separately or may take the whole examination together. He will be required to produce the certificates required by the regulations before being admitted to the respective parts of the examination. A candidate who produces evidence of having passed an examination for a degree in medicine in the subjects of Pathology and Bacteriology at a University recognised by the Board is exempted from Section I. The fee for admission to Section I. is £4 4*s*.; for admission to Section II., Part I., £10 10*s*.; Part II., £10 10*s*.; Part III., £6 6*s*.; and the re-examination fees are respectively £3 3*s*., £6 6*s*., £6 6*s*., and £4 4*s*.

Students of recognised universities in England, Scotland, and Ireland, who have passed examinations for a degree in Medicine at their universities in the subjects of the First Examination of the Examining Board, may enter for a part of the Final Examination at the expiration of two years from the date of passing in Anatomy and Physiology on production of the required certificates, but they must complete 33 months of clinical study before examination.

Members of certain recognised Indian, Colonial, and Foreign universities who have passed examinations for the Degree of Doctor or Bachelor of Medicine or Surgery in the subjects of the First and Second Examinations of the Examining Board under the old Regulations, or of the First Examination and Section I. of the Final Examination under the new Regulations, may present themselves for the Final Examination under special conditions. The Board also grants Diplomas in Public Health, in Psychological Medicine, in Ophthalmic Medicine and Surgery, in Tropical Medicine and Hygiene, and in Laryngology and Otology. Candidates must hold a Medical qualification registrable in the United Kingdom or be Graduates in Medicine of a recognised Indian, Colonial, or Foreign University. Particulars and conditions of admission to all examinations, fees, &c., may be obtained from the Secretary of the Examining Board, Examination Hall, Queen-square, Bloomsbury, London, W.C. 1.

ROYAL COLLEGE OF PHYSICIANS OF LONDON:
THE MEMBERSHIP AND FELLOWSHIP.

The College confers two separate diplomas—the *Fellowship*, a purely honorary distinction, and the *Membership*, obtained by examination.

Membership.—The age for admission to this diploma, it will be noticed, has been changed from 25 to 23 years. The alteration in the by-law of t College is designed to enable men who have j finished house appointments to sit for an examinat for which their recent clinical experience has exac fitted them. The candidate must either have pass the examinations for the licence of the College, else be a registered medical practitioner who h obtained the degree of Doctor or Bachelor of Medic at a University recognised by the Censors Boa The examination is directed partly to patholo and partly to the practice of medicine. Credit also given to candidates who show a knowledge Latin, Greek, French, or German. Further inform tion may be obtained from the Registrar at t College. The fee for admission as a Member of t College is 40 guineas, except when the candidate membership is a licentiate of the College, in wh case the fee already paid for the licence deducted from the 40 guineas. The fee for t examination is 8 guineas, which is reckoned part of the fee for admission in the case success.

Fellowship.—The *Fellows* are selected annua from the ranks of the *Members* by the Comitia of College.

ROYAL COLLEGE OF SURGEONS OF ENGLAND:
THE FELLOWSHIP.

The Royal College of Surgeons of England con its diploma of Fellow upon a few distinguished pers in an honorary capacity. Two Members of l standing may also be elected to the Fellows annually. But the bulk of the Fellows obtain diploma as the result of examination.

Fellowship.—The examination for the Fellowshi divided into two parts—viz., the First Examinat and the Second Examination. The subjects of First Examination are Anatomy and Physiology, those of the Second Examination are Surgery, includ Surgical Anatomy and Pathology. The examinati are partly written and partly vivâ voce, and incl the examination of patients and the performance operations on the dead body. The First Exami tion will in future years be held in June December and the Second Examination in May November.

The fees for examination are: First Examinati first admission 8 guineas, and for each readmiss 5 guineas. Second Examination, each admiss 12 guineas. The fee payable on admission to Fellowship by Members is 10 guineas and by n Members 30 guineas, in addition to examination f

A Member of the College is admissible to the F Examination at any time after receiving his Diplo of Membership. A candidate who is not a Membe admissible after passing the First Professional Exa nations of the English Conjoint Board in Anato and Physiology, or the equivalent examination in University, on the production of certificates attendance upon prescribed courses.

A Member of the College is admissible to the Sec Examination at any time after having passed First Examination, on producing evidence of hav been engaged not less than six years in the st (or study and practice) of the profession.

A candidate who is not a Member of the Col must possess the registrable surgical and med degrees of universities recognised by the Council must have been engaged in the study (or study practice) of the profession for not less than four y subsequent to the date of obtaining the recogn qualification, one year of which shall have been sp in attendance on the Surgical Practice of a recogn hospital. The diploma of Fellow is not confe upon successful candidates until they have attai the age of 25 years.

The Regulations may be obtained on applicatio the Director of Examinations, Examination H Queen-square, Bloomsbury, London, W.C. 1.

SOCIETY OF APOTHECARIES OF LONDON.

The Primary examination is held quarterly. rt I. includes Chemistry, Chemical Physics; Prac- al Chemistry; Materia Medica and Pharmacy. rt II. includes Anatomy, Physiology, and Histo- gy. This examination cannot be passed before the mpletion of twelve months' Practical Anatomy th Demonstrations, and these subjects cannot be ken separately except in the event of the candidate ving previously passed in one.

The Final examination is held monthly except in ptember. Part I. Clinical Surgery: Principles and actice of Surgery, Surgical Pathology, and Surgical natomy, Operative Manipulation, Instruments, and pliances. Part II. Clinical Medicine: Medicine, armacology, Pathology, and Morbid Histology; rensic Medicine, Hygiene, Theory and Practice of ccination; and Mental Diseases. Part III. includes dwifery, Gynæcology, and Diseases of New-born ildren and the Use of Obstetric Instruments.

The course of study for the *Final examination* ludes attendance on the Surgical and Medical actice, with Post-mortem Examinations, at a spital connected with a medical school for a period three winter and three summer sessions, including ourse of Practical Midwifery, with attendance on 20 dwifery cases. The course of medical study must tend over five years, and the office of dresser or nical clerk must be held at a hospital or other titution recognised by the Society. Three years ust elapse after a candidate has passed the examina- n in Anatomy and Physiology before he can mplete the Final examination.

Evidence shall also be given of practical instruction Infectious Diseases and in Mental Diseases (at a natic asylum or in the wards of an institution con- ining a special ward set apart for the treatment of ental diseases), and in any two of the following bjects: Ophthalmic Surgery, Laryngology with inology and Otology, Dermatology, and Diseases Children. Candidates intending to present them- ves for examination are required to give 14 days' tice. The fee for the Licence is 20 guineas. Female ndidates are admitted to examinations. The exami- tion offices are open from 10 A.M. to 4 P.M.; on turdays from 10 A.M. to 1 P.M. All letters should be dressed to the Secretary, Court of Examiners, ciety of Apothecaries of London, Blackfriars, E.C. 4.

ETROPOLITAN CENTRES AFFORDING POST-GRADUATE FACILITIES.

In addition to the medical schools already dealt th, the following institutions provide, in certain cumstances, for the needs of the medical student his curriculum and for the post-graduate student quiring special forms of instruction and opportunities clinical observation. Many of the institutions recognised by the English Conjoint Examining ard as a place of study for the fifth year of the rriculum.

In each case further information concerning the actice of the hospital, the fees, and the appointments n be obtained from the Secretary of the Hospital the Secretary of the Medical Committee.

Certain hospitals or groups of hospitals are working conjunction with the Fellowship of Medicine d Post-graduate Medical Association. This associa- n, which has its offices in the Buildings of the Royal ciety of Medicine, 1, Wimpole-street, W. 1, provides ensive courses in general and special branches of edicine and surgery, which are arranged at short ervals, and also courses in special subjects the ture of which are indicated by the groups of spitals coöperating in its teaching work. Member- ip of the Fellowship is open to all qualified medical actitioners, the subscription fee being 10 shillings r annum. Full information regarding the courses study can be obtained from the Secretary. The Post-graduate Medical Journal, the official organ of the Fellowship, is published monthly at 1, Bedford-street, Strand, W.C.

SPECIAL DIPLOMAS.

Special diplomas in public health, tropical, psychological, and ophthalmic medicine, medical radiology and electrology, laryngology, otology, and tuberculosis are now granted in proof of intensive work along the different lines indicated. Of these, the Diploma in Public Health, being regulated by the General Medical Council, is registrable. Appointments to and promotion in the various Services are largely dependent on the possession of a particular diploma, and each syllabus of the special courses available at the institutions which follow, either with or without association with the Fellowship of Medicine, is planned to afford the necessary instruction.

The special instruction given at the Bethlem Royal Hospital and the Maudsley Hospital, in connexion with the Diploma in Psychological Medicine is referred to later.

HOSPITALS OF THE METROPOLITAN ASYLUMS BOARD.—These are divided into infectious hospitals and institutions for the treatment of tuberculosis and of venereal diseases. In the metropolis and the near vicinity there are 18 of these institutions at which medical instruction can be received in clinical and administrative work especially in connexion with the candidature for Diplomas in Public Health. The Metropolitan Asylums Board announces a course of lectures and demonstrations (three months) on clinical practice and in hospital administration, to be given at the North-eastern Hospital, St. Ann's-road, Tottenham, N. 15, by the medical superintendent, on Mondays and Wednesdays at 4.45 P.M., and alternate Saturdays at 11 A.M., beginning Monday, 3rd October, 1927. This course complies with the requirements of the revised D.P.H. regulations of the General Medical Council. Application for further information should be made to the Clerk to the Metropolitan Asylums Board, Victoria Embankment, London, E.C. 4.

SEAMEN'S HOSPITAL SOCIETY.—Although a qualification in tropical medicine has not been made registrable by statute, a diploma is regarded as indispensable for appointments in the Colonial Medical Service and similar positions abroad. Systematic instruction for these diplomas is given at the London School of Hygiene and Tropical Medicine, 23, Endsleigh-gardens, Euston-road, N.W. 1. The society possesses four hospitals—the Dreadnought Hospital at Greenwich, 250 beds, and the Branch Hospital in the Royal Victoria and Albert Docks, E., 53 beds; the Hospital for Tropical Diseases, Endsleigh-gardens, London, N.W. 1, 58 beds; Tilbury Hospital, Tilbury Docks, Essex, 65 beds; King George's Sanatorium for Sailors, Bramshott, Hants, 80 beds, and the Angas Home, Cudham, 36 beds. Total, 542 beds. It has also a Dispensary in the East India Dock-road from which patients are transferred to the hospitals. In conjunction with the Fellowship of Medicine arrangements have been made for a course of operative surgery. The London School of Hygiene and Tropical Medicine is making a valuable provision for the study of advanced bacteriology at 6, Gordon-square, W.C., in October next. Well in advance of the needs to be met when the arrangements are complete for the Diploma of Bacteriology, to be instituted by the University of London.

A similar course of instruction, is given at the Incorporated Liverpool School of Tropical Medicine.

GENERAL PRACTICE.

ROYAL NORTHERN GROUP OF HOSPITALS.—The Royal Northern Hospital, Holloway, London, N. 7, is the main institution of the Royal Northern Group of Hospitals, which includes the Royal Chest Hospital, City-road, E.C., Hospital of Recovery, Southgate, and the Reckitt Convalescent Home, Clacton-on-Sea.

The total number of beds in the group is 394. Besides the honorary staff there are six anæsthetists, three pathologists, resident medical officer, resident house physician, three resident house surgeons, two resident casualty officers, and one resident obstetric surgeon. The large rectangular and circular wards, each of which contains 25 beds, the children's ward for children under 5 years of age, the observation wards in the new Casualty Department, the two operation theatres, and out-patient department are designed with a view of offering the greatest facilities for clinical work. The Special Departments include the following: Fracture, genito-urinary and neurological, physico-therapeutic, pathological (under a director of clinical pathology), tuberculosis, and venereal diseases. Patients are removed to the Hospital of Recovery by ambulance a few days after operation. Demonstrations are given daily in the wards and out-patient departments. Clinical assistants (qualified), clinical clerks, and pathological clerks are appointed in the general and special departments and may receive certificates at the end of their terms of office. A new maternity department has been opened, and the light department has been re-equipped.

Post-Graduate Facilities.—Weekly lectures by members of the hon. medical and surgical staff are free to all medical practitioners. Special classes and demonstrations are being arranged for post-graduates. They include instruction in General Medicine and Surgery, and also lectures and demonstrations in special subjects at the Royal Northern and Royal Chest Hospitals.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N. 15.—This hospital is in the midst of a densely populated neighbourhood and contains medical, surgical, gynæcological, and children's wards, having 200 beds. There are special departments for gynæcological cases, diseases of the eye, ear, throat, and nose, skin diseases, plastic surgery, medical electricity, radiography, and dentistry. Operations are performed every afternoon of the week (except Saturday) at 2.30 P.M. Clinical instruction, ordinarily including laboratory classes, and lectures are given in the wards and out-patient departments, laboratories, and lecture hall in connexion with the North-East London Post-Graduate College attached. There are five resident medical officers, and clinical assistants are appointed under certain conditions. Special intensive post-graduate courses are also held at intervals throughout the year. Further particulars in regard to the hospital may be obtained from Dr. S. C. Shanks, Secretary to the Medical Committee, 87, Harley-street, W. 1; or from Dr. A. J. Whiting, Dean of the College, 19A, Cavendish-square, W. 1.

WEST LONDON HOSPITAL, Hammersmith, W.—This hospital has 210 beds. Attached to the hospital is the West London Post-Graduate College. The practice of the hospital is reserved exclusively for qualified men. Instruction is given in the medical and surgical out-patient rooms and demonstrations are given in the wards. Clinical assistantships are obtainable in the various general and special out-patient departments. Special classes are held in Diseases of the Throat and Nose, Skin, and Eye, and in Gynæcology, Medical Electricity, Operative Surgery, Bacteriology, Anæsthetics, Intestinal Surgery, Medical and Surgical Diseases of Children, Blood and Urine, Clinical Microscopy, Cystoscopy, Venereal Diseases, and Operative Ophthalmology, Radiography, X Ray Therapy. The accommodation for post-graduates consists of a lecture room, together with reading, writing, and class rooms. The hospital has a fully equipped pathological laboratory, at which instruction is given in elementary bacteriology. The certificate of the hospital is accepted by the Admiralty, War Office, Colonial Office, and India Office in cases of study leave. Further information can be obtained on application to the Dean, Sir Henry Simson, at the Hospital. Secretary of the Post-Graduate College Mr. C. Cole, and of the Hospital Mr. H. A. Madge.

LONDON TEMPERANCE HOSPITAL, Hampstead-roa N.W. (Established 1873; Incorporated 1917.)—T hospital contains 135 beds. The medical a surgical practice of the hospital is open to studen and practitioners. Operations: Monday, 1.30 P.M Tuesday, 2.30 P.M., Wednesday, 9 A.M. and 1 P.M Thursday, 8 A.M., Friday, 10 A.M. and 3 P.M., a Saturday, 9 A.M. New Out-patient Departments f special diseases have been opened: Neurolog Diseases of the Stomach and Disorders of Digesti Diseases of Women, Genito-urinary Diseases, Disea of the Rectum, and Dermatology.

HAMPSTEAD GENERAL AND NORTH-WEST LOND HOSPITAL.—In-patient Department: Haverstock H N.W.; Out-patient Department: Bayham-stre Camden Town (130 beds—viz., 102 free, 8 isolation a observation, &c., and 20 paying or contributory). Ser Hampstead and the populous districts of Kentish To and Camden Town. The out-patients, with the exce tion of Hampstead casualty and emergency cas attend exclusively at the Out-patients' Departme Bayham-street, Camden Town. Further particul from the Secretary at the hospital. Post-gradua work is in connexion with the Fellowship Medicine.

QUEEN MARY'S HOSPITAL, Stratford.—This hospi has developed from the West Ham and East General Hospital. It has 200 beds and minist to a very poor public. Founded as a dispens in 1861, and developing into a hospital in 1890, stea extensions have been made during this centu A Royal Charter was obtained in 1917, and the hospi has become a valuable charity with a full medi staff of physicians and surgeons, and specialists gynæcology, obstetrics, ophthalmological surge radiology, and dental surgery. The Fellowship Medicine and Post-graduate Medical Association mal frequent use of the opportunities here offered.

NEUROLOGY.

THE NATIONAL HOSPITAL, QUEEN-SQUARE, W.C. The hospital, with the Convalescent Home at E Finchley and branch at Clapham Park, contains 2 beds and cots. The out-patient physicians attend eve Monday, Tuesday, Thursday, and Friday at 2 P.M. and the physicians daily. Clinical clerks a appointed under physicians and clinical assistants out-patient physicians. Post-graduate Courses Lectures and Demonstrations are held three tim every year, usually commencing in January, May, a October, and lasting eight weeks. Special Courses Neurological Ophthalmology, Neuropathology, a the Anatomy and Physiology of the Nervous Syst are given. The Pathological Laboratory is availa for special work under the Pathologist.

WEST END HOSPITAL FOR NERVOUS DISEASES. A course of Practical Pharmacy is given by the dispenser. Fees on application. Applications should be made to the Honorary Secretary of the Medical Committee.

WORCESTER GENERAL INFIRMARY, Worcester.—This hospital has 132 beds. Pupils are taken by members of the Honorary Medical and Surgical Staff. New X Ray and Electrical and Wolfram Arc Light, Ear, Nose and Throat, and Orthopædic Departments have been erected and are now in use. Additional accommodation for the Honorary Staff and Out-patients and also an Outdoor Shelter in connexion with the Children's Ward have been built as a memorial to King Edward VII., and fire-escape staircases erected.

YORK COUNTY HOSPITAL, York.—This hospital contains 170 beds. There are balconies for outdoor treatment, two installations of X ray apparatus, electrotherapeutic and massage department, and clinical laboratory. A Venereal Diseases Clinic is held.

The hospitals vary much in size and scope, and obviously offer, for reasons of geography, many separate appeals, so that no detailed information upon any particular points in reference to any particular institution would be of service to any large group of students. It is unnecessary to point out to the general practitioners in the neighbourhood the advantages to be obtained from the post-graduate facilities offered to them by the hospital in their midst, and it is gratifying to know that a far wider use is being made of these facilities than was formerly the case.

Medical students completing their curriculum by attendance at authorised courses in these hospitals must ascertain, by communication with the Secretary, information concerning fees and other details.

PHARMACEUTICAL SOCIETY.

SCHOOL OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN (recognised by the UNIVERSITY OF LONDON).—The Pharmaceutical Society conducts examinations for registration as (*a*) Chemist and Druggist and (*b*) Pharmaceutical Chemist. For registration as Chemist and Druggist the candidate must pass (i) the Preliminary Scientific Examination (subjects Chemistry, Physics, and Botany); and (ii) the Chemist and Druggist Qualifying Examination (subjects Pharmacognosy, Pharmacy, Pharmaceutical Chemistry, and Forensic Pharmacy). Fee for each examination, 6 guineas; for each subsequent examination after failure, 4 and 6 guineas respectively. The advanced or Major Examination (for registration as Pharmaceutical Chemist) includes Botany, Chemistry, Physics, Practical Chemistry, and Materia Medica. Fee, 3 guineas. The last Major Examination will be held in July, 1928. The Pharmaceutical Chemist Qualifying Examination (for registration as Pharmaceutical Chemist) includes Botany, Chemistry, Pharmacognosy, Pharmacy, and Forensic Pharmacy. Candidates must have passed the Preliminary Scientific Examination. Fee, 12 guineas: for each subsequent examination after failure, 6 guineas. Courses of Instruction are given for the Chemist and Druggist Qualifying Examination, and (two years' course) for the Pharmaceutical Chemist Qualifying Examination in conjunction with University College.

An Intercollegiate, two years' course for the Final Examination for the degree of B.Pharm. of the University of London is also given in conjunction with University College. Medical students are admitted to the lectures and laboratory work in any or all the courses. Certificates of instruction in the School are received by the Conjoint Board of the Royal Colleges and by the University of London. Graduates in Science may carry out the research work necessary for the thesis for the Ph.D. of the University of London in the Society's Research Laboratories. Application for admission to the school, or for further information, may be made to the Dean, Prof. Greenish, 17, Bloomsbury-square, London, W.C. 1.

II.—SCOTLAND.

THE UNIVERSITIES.

UNIVERSITY OF EDINBURGH.

Four Degrees in Medicine and Surgery are conferred by the University of Edinburgh—viz., *M.B.*, *Ch.B.*, *M.D.*, and *Ch.M.* The degree of *Ch.B.*, cannot be conferred on any person who does not at the same time obtain both degrees, and no one is admitted to the degrees who has not been engaged in Medical and Surgical study for five years.

Candidates for the degrees of M.B. and Ch.B. must have attended for at least three academic years the medical and surgical practice either of the Royal Infirmary, Edinburgh, or of a general hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons. They must have attended courses of instruction in Clinical Surgery and Clinical Medicine each of nine months, and courses of instruction in all the subsidiary subjects. They must have attended a course of instruction in Clinical and Practical Midwifery and have personally conducted 12 cases of labour.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations have effect:—Three of the five years of medical study must be spent in the University of Edinburgh. The remaining two years may be spent in any University of the United Kingdom, or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teacher as may be recognised for the purpose by the University Court.

Women are admitted to graduation in medicine under the same conditions as men.

Bachelors of Medicine and *Bachelors of Surgery* may proceed to the degrees of *Doctor of Medicine* and *Master of Surgery* after they have spent one year in the medical or surgical wards respectively of a hospital, or the Military or Naval Medical Services, or in scientific work bearing directly on their profession, or two years in practice. In each case an examination must be passed and a thesis submitted for approval of the Faculty.

Post-Graduate Instruction.—The University takes part in the Courses given under the auspices of the Edinburgh Post-Graduate Courses in Medicine. In the departments of the Faculty of Medicine provision is made for research by students of graduate standing. In the University laboratories facilities will be provided for candidates for the Degree of Ph.D. whose applications to engage in research have been accepted by the Senatus.

In connexion with the University and Royal Colleges Post-Graduate Instruction is given each year, chiefly in the Summer Vacation (July–September). Special Courses are arranged for, and particulars may be had on application to the Hon. Secretary, Post-Graduate Courses in Medicine, University New Buildings, Edinburgh.

The University of Edinburgh is especially rich in scholarships and prizes in medical subjects.

Full particulars concerning these, as well as concerning the fees at different stages, can be obtained from the Dean of the Medical Faculty.

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, Edinburgh.—The number of students varies much in the classes and subjects. It is within the limit to say that about 1000 students avail themselves each session of the opportunity of attending the school. The lectures qualify for the University of Edinburgh and other Universities, the Royal Colleges of Physicians and Surgeons of London, Edinburgh, and Dublin, the Faculty of Physicians and Surgeons of Glasgow, and other Medical and Surgical and Pu Boards. Special courses of instruction for de students are also included in the curriculum of h school.

The practical classes and laboratories will open n the lectures commence on Oct. 4th.

In accordance with the statutes of the Universit Edinburgh one-half of the qualifying classes requ for graduation may be attended in this school. h regulations require that the fee for any class t e for graduation in Edinburgh shall be the sam that for the corresponding class in the Univer The whole education required for gradua at the University of London may be taken in h school.

Post-graduate Courses are conducted in conjunc with the University.

Further particulars regarding the school, also calendar (price 6*d.*) may be had on application to Dean of the School, Edinburgh.

ROYAL INFIRMARY, Edinburgh.—994 beds 42 cots for children. The clinical work of Edinburgh student is done at the Royal Infirm Courses of Clinical Medicine and Surgery are g by the physicians and surgeons to male and fe students. Special instruction is given on Dis of Women, Physical Diagnosis, Diseases of Skin, Diseases of the Eye, the Ear, the Lar and the Teeth. Separate wards are devote Venereal Diseases, Diseases of Women, Disease the Eye, the Ear, Throat and Nose, and the S and also to cases of Incidental Delirium or Insa There is also a large and complete Radiolo Department. Post-mortem examinations are c ducted in the anatomical theatre by the patholo and his assistants, who also give practical instru in Pathological Anatomy and Histology.

The appointments are: 1. Resident physi and surgeons are appointed and live in the house of charge. The appointment is for six months, may be renewed at the end of that period by sp recommendation. 2. Non-resident house physi and surgeons and clinical assistants are appointe six months. The appointment may be renewed like period by special recommendation. 3. Clerks dressers are appointed by the physicians and surg These appointments are open to all students junior practitioners holding hospital tickets. Assistants in the Pathological Department appointed by the pathologist.

Facilities are given in connexion with the l graduate Courses arranged by the Edinburgh Un sity and the two Royal Colleges jointly.

ROYAL HOSPITAL FOR SICK CHILDREN, Scie road, Edinburgh.—120 beds, and is fitted with e modern improvement. A fully equipped out-pa department (medical and surgical) is condu daily. Systematic courses of instruction, which qu for graduation in the Edinburgh University elsewhere, are given thrice throughout the yea the staff. Each course consists of 50 meetings combines medicine and surgery. Post-grad Courses of Lectures are held during the sum vacation. Full particulars can be obtained fro Registrar at the hospital.

EYE, EAR, AND THROAT INFIRMARY OF E BURGH (with which is incorporated the Edinb Eye Dispensary), 6, Cambridge-street, Lothian-roa Clinical Lectures and Instruction are given in institution, which is open at 1 o'clock daily for door patients for Eye Diseases; Mondays, Thurs and Saturdays at 12 noon, and Tuesdays and Fri at 4 P.M. for outdoor Ear, Nose, and Throat Pati Patients whose diseases require operations or e care are accommodated in the house (10 b Practical Ophthalmoscopic Classes may be arran and Clinical Assistants are appointed from tim

A post-graduate course in Diseases of the Ear, , and Throat is held each academic term, com- cing in May, October and January, and continuing six weeks. The next course commences in ber. The class meets at 5 P.M. on Tuesdays Fridays, and the instruction, which is practical, pplemented by lantern demonstrations. Full iculars from the Secretary, 32, Charlotte-square.

UNIVERSITY OF GLASGOW.

he University of Glasgow is both a teaching and a ee-granting body, but admits to graduation only idates whose preliminary examination and course tudy conform to its own regulations. Within in limits instruction given by recognised medical ols and teachers may be accepted, but not less one-half of the subjects other than clinical must aken in this or some other recognised university, at least two years of the course must be taken in gow University. Seven degrees, open both to men women, are conferred: *M.B.* and *Ch.B.* (always ointly), *M.D.* and *Ch.M.*; *B.Sc.* in Public Health; . in Public Health; *B.Sc.* in Pharmacy; and). in the Faculty of Medicine. A Diploma in ic Health (*D.P.H.*) is also granted.

l information as regards the extent and standard he Preliminary Examination may be obtained by ication to the Secretary, Scottish Universities ance Board, 81, North-street, St. Andrews.

r the degrees of M.B. and Ch.B. a curriculum of years is required. The candidate must attend ourse or courses of instruction in each he following subjects of study, extending not less than the number of terms specified ach case, and including such class exami- ns as may be prescribed in connexion with several courses:—Chemistry (including Organic nistry), two terms; with Practical Chemistry, term; Physics (with practical work), one term; ny (with practical work), one term; Zoology practical work), one term; Anatomy and tical Anatomy, five terms; Physiology and tical Physiology, three terms; Materia Medica Therapeutics (together or separately), each ect, one term; Pathology and Practical Patho- three terms; Medical Jurisprudence and Public th (together or separately), each subject, one ; Midwifery and Diseases peculiar to Women to Infants, two terms; Surgery, two terms; cine, two terms. Candidates must attend for ast three years the Medical and Surgical Practice recognised hospital accommodating at least atients and having a distinct staff of physicians surgeons. At least nine months' hospital attend- is required on both Clinical Surgery and Clinical cine with nine months more of general hospital tice; the student must have acted for six ths as clerk in medical and dresser in surgical ls, and must have had six months' outdoor tice; he must also have attended a course of tal Diseases and of Practical Pharmacy (25 ings), must have been properly instructed in ination at a public vaccination station, and have attended at least 20 cases of labour the Practice of a Lying-in Hospital. The rsity also requires further study in various al subjects.

here are four Professional Examinations, the first prising Botany, Zoology, Physics, and Chemistry; second comprising Anatomy and Physiology; hird comprising Materia Medica and Therapeutics Pathology; and the fourth or final, comprising ical Jurisprudence and Public Health, Surgery Clinical Surgery, Practice of Medicine and ical Medicine, and Midwifery and the Diseases liar to Women and to Infants.

he degrees of M.D. (*Doctor of Medicine*) *and Ch.M.* *ster of Surgery*) are granted to candidates, not r 24 years of age, who have previously obtained the double bachelorship on completing examinations, in Clinical Medicine for M.D. and in Surgical Anatomy, operations on the dead body, and Clinical Surgery for Ch.M. The higher degree of Doctor of Philosophy (Ph.D.) is also conferred in the Faculty of Medicine. Candidates must already have obtained a degree (or equivalent diploma) from an approved University or College and must prosecute a course of special study or research for two or three years and given evidence of satisfactory progress. A thesis must be presented for approval by the Senate on the recommendation of a Special Committee. The candidate may be required to undergo an oral or other examination on the subject matter of the thesis. Post-graduate Medical Teaching is available under the auspices of Glasgow Post-Graduate Medical Association. This Association is representative of practically all the Teaching Institutions in Glasgow. Weekly demonstrations for practitioners are given throughout the winter and spring, and comprehensive courses of instruction during the summer and autumn. There is a General Medical and Surgical Course, during the last two weeks of August and the first two weeks of September. This is a whole-time course and includes most of the subjects of interest to the general practitioner. The forenoons are occupied with General Medicine and Surgical Diagnosis and Minor Surgery in the Royal Infirmary and in the Victoria Infirmary. In the afternoons special subjects are dealt with in some of the special hospitals or in the special departments of the general hospitals—two subjects each afternoon. On the four Saturday forenoons Tuberculosis and Infectious Fevers are demonstrated at Ruchill Fever Hospital. Arrangements have also been made whereby a limited number of graduates may become attached to wards or out-patient departments nominally as clinical assistants for definite periods throughout the year. As such they work under the direct supervision of the physician or surgeon in charge, and carry out such detailed investigations as directed. Further information may be obtained from the Secretary of the Association, 7, Woodside-terrace, Glasgow.

Bursaries, Scholarships, and Prizes.—Bursaries and Prizes to the annual amount of over £1000 are appropriated to students in the Medical Faculty, and there are also several Scholarships and Fellowships which may be held by medical students who have gone through the Arts course. A full list will be found in the Calendar.

The great majority of the students take their hospital course at the Western, Royal, and Victoria Infirmaries, and at the district hospitals of Glasgow Parish Council, where clinical instruction is given by professors of the University and others. Clinical instruction on Fevers is given at Ruchill and Belvidere Hospitals, while special courses, largely of a practical nature and embracing work in Hospital or Asylum wards, are conducted by University Lecturers on the Ear, the Throat and Nose, Dermatology, Ophthalmology, Venereal Diseases, Tuberculosis, Insanity, and Electro-diagnosis and Therapeutics. Queen Margaret College, sometime conducted as a separate institution for the higher education of women, was made over to the University in 1892, and in it certain medical classes for women are conducted under lecturers appointed by the University Court.

QUEEN MARGARET COLLEGE (Women's Department of the University).—This is an integral part of the University of Glasgow. The classes are taught by professors of the University and other lecturers appointed by the University Court, and it is governed by the University Court and Senate. The curricula, regulations, and fees are the same as those of the male students, and the University degrees are open to women on the same conditions as to men. The School of Medicine is a special feature of the College, and gives full preparation for the medical degrees of the University. The women students attend classes

in the various University Buildings at Gilmore-hill and Queen Margaret College, the Royal Infirmary, the Western Infirmary, and the Victoria Infirmary. Facilities for clinical work are given in the Royal, Western and Victoria Infirmaries, in the Maternity, Royal Sick Children's, and other hospitals. The Arthur Scholarship is open every third year to students of first year; other Bursaries are open in Arts and Medicine, and women are admitted to certain University bursaries and fellowships.

THE ANDERSON COLLEGE OF MEDICINE, Dumbarton-road, Glasgow, W.1.—Courses are given which qualify for all the licensing boards and for the Universities of Oxford, Cambridge, London, Durham, Edinburgh, and Glasgow (the latter two under certain conditions). Extensive accommodation is provided for Practical Anatomy, Practical Chemistry, Practical Botany, Practical Zoology, Practical Physiology, Practical Pharmacy, Operative Surgery, and Public Health. Ample provision has also been made for the comfort of students. Women students are admitted on the same terms as men, and the Carnegie Trust extends its benefactions to students of the College. (Full particulars may be obtained from the Carnegie Trust Offices, Merchants' Hall, Edinburgh.)

Candidates for the L.D.S. can obtain the full medical curriculum in Anatomy, Chemistry, Physiology, Surgery, Practice of Medicine, and Materia Medica. The courses special to Dentistry are conducted at the Dental Hospital, Glasgow.

Communications relating to the College to be addressed to the Secretary of the Medical Faculty, Communications relating to the Preliminary Examination in General Education to be addressed to the Educational Institute Office, 47, Moray-place, Edinburgh; and relating to the Triple Qualification and to the Dental Qualification to be addressed to Royal Faculty Hall, 242, St. Vincent-street, Glasgow.

ST. MUNGO'S COLLEGE AND GLASGOW ROYAL INFIRMARY.—The classes in St. Mungo's College qualify for the medical qualifications of the English, Scotch, and Irish Conjoint Boards, for the dental diplomas of the English, Irish, and Scottish Boards and, under certain conditions, for the various universities, including the University of London. Students who have fulfilled the conditions of the Carnegie Trust are eligible for the benefits of this Trust during the whole course of their studies at St. Mungo's College.

Further particulars can be obtained from a syllabus which may be procured free on application to the Secretary of the Medical Faculty, 86, Castle-street, Glasgow.

ROYAL INFIRMARY, Glasgow.—The ancient connexion between the University of Glasgow and the Royal Infirmary was revived in 1911, when four University Chairs and several University Lectureships were established at the Infirmary. New Lectureships in Materia Medica and Pathological Biochemistry were established last year. St. Mungo's College which embraces and continues the original Royal Infirmary Medical School, is situated in the infirmary grounds. The infirmary has, including the Ophthalmic Department, 700 beds. There are special wards for diseases of women, of the throat, nose and ear, skin, eye, burns and septic cases. The wards are open to Women Students. In addition to the large medical and surgical departments there are departments for special diseases—viz., diseases of women, of the throat and nose, of the ear, of the eye, of the skin, and of the teeth. Five house physicians and 10 house surgeons, who board in the hospital free of charge, are appointed every six months. Clerks and dressers are appointed by the physicians and surgeons. As a large number of cases of acute diseases and accidents of a varied character are received these appointments are very valuable and desirable. There is a modern and fully equipped Electrical Pavilion and Massage Department, and year by year the latest and most approved apparatus for diagnosis and treatment has been added. Post-graduate Cla[s]es are held during August and September in Clin[i]al Medicine, Clinical Surgery, Clinical Gynæcolo[g]y, Diseases of the Skin, Biochemistry, Diseases of [t]e Throat, Nose and Ear, and in Diseases of the E[a]. Tutorial Classes for senior students are also h[e]d in August and September.

For information regarding fees and other particul[a]s, application should be made to the Superintendent.

GLASGOW WESTERN INFIRMARY.—This hospita[l] of 600 beds adjoins the University. Special wards [a]re set apart for Diseases of Women, Throat, Nose, [a]nd Ear, and for Affections of the Skin. In the out-pati[e]nt department there are special clinics for Diseases [o]f Women and for Diseases of the Throat, Ear, Te[e]th, Skin, Venereal Disease, and Electro-Therapeutics. [T]he Clinical Courses are given by the physicians and [s]ur-geons, each of whom conducts a separate class, [a]nd students require to enter their names at the beginn[i]ng of the session for the class which they propose [t]o attend. Special instruction is given to junior stude[n]ts by tutors or assistants, and clinical clerks and dres[s]ers are selected from the members of the class. All [t]he courses of clinical instruction are recognised by [t]he University of Glasgow and the other boards [i]n the kingdom. In the Pathological Department [t]he course is both systematic and practical, also po[s]t-graduate courses, and extends through the winter [a]nd following summer; these are likewise recognised [b]y the University for graduation. Eighteen resid[e]nt assistants are appointed annually, without sala[r]y, from those who have completed their cou[r]se. A Clinical Laboratory has been opened, and stude[n]ts receive laboratory instruction from the lecturer [i]n clinical methods. A School of Massage, Medi[c]al Electricity, and Swedish Remedial Exercises [h]as been established to qualify for the Certificate of [t]he Chartered Society of Massage and Medical Gymnasts.

Secretary: J. Matheson Johnston, C.A., 87, Un[i]on-street.

ROYAL HOSPITAL FOR SICK CHILDREN, Glasgow.—This institution consists of: (1) a hospital at York-[h]ill containing 270 cots built on an elevated and cen[t]ral site close to the University and opened in July, 19[1]; (2) a Dispensary, or Out-patient Department, in W[e]st Graham-street, opened in October, 1888; and (3) [a] country branch at Drumchapel, Dumbartonsh[i]re, containing 30 cots, opened in 1903. Children trea[t]ed must not be over 13 years of age, nor suffer fr[o]m infectious diseases. There are one professorship [a]nd two lectureships in the University of Glasgow [i]n connexion with the hospital, one professorship [a]nd one lectureship on the Medical Diseases of Infa[n]cy and Childhood, and one lectureship on Surgery [a]nd Orthopædics in Relation to Infancy and Childho[o]d. The lectures are both systematic and clinical, [b]ut particularly and chiefly the latter. In addition spe[c]ial facilities are given for post-graduate study.

Full information may be obtained from the Medi[c]al Superintendent.

GLASGOW ROYAL MATERNITY AND WOME[N]'S HOSPITAL, Rottenrow.—114 beds. A Maternity [a]nd Child Welfare Centre has been established consist[i]ng of a complete In-door and Out-door Antena[t]al Department and an Infant Consultation Clinic. A new research laboratory was opened last year. Full particulars as to fees and accommodation may [b]e obtained from the House Superintendent at [t]he hospital.

ROYAL SAMARITAN HOSPITAL FOR WOMEN, Glasg[o]w.—Increased to 160 beds by building extensi[o]ns completed last year. It offers excellent facilities [f]or clinical instruction in the diseases peculiar to wom[e]n. Lectures and clinical demonstrations are given [b]y members of the surgical staff to students and to p[o]st-graduates; and the hospital is represented on [t]he Board of the Glasgow Post-Graduate Medical Asso[c]iation formed for coördinating post-graduate medi[c]al teaching in all the hospitals. The Royal Samari[t]an

tureship in Gynæcology is a University Lectureship ociated with the Hospital.

or further information application may be made he Hospital, or to the Secretary, 149, St. Vincent- et, Glasgow.

LASGOW LOCK HOSPITAL, 41, Rottenrow, Glasgow. tains 80 beds for the treatment of females suffering n Venereal Diseases. There is also a Labour rd, and a well-equipped Dispensary for out-patient ndances. There is a Lecture Room and a oratory, equipped with modern appliances. Post- duate classes are also held. Recently the hospital been completely renovated and modernised. l information from the Secretary and Treasurer, J. Neilson Gray, LL.B., 65, Bath-street, Glasgow.

LASGOW OPHTHALMIC INSTITUTION, 126, West ent-street, and 131, Wellington-street (30 beds six cots).—This institution is administered by Royal Infirmary. Clinical and systematic courses ectures for students during the winter and summer sions. Operations on Wednesdays and Fridays. t-graduate classes and demonstrations are arranged ing the summer. Secretary and Cashier: R. rrison Smith, C.A., 135, Buchanan-street, Glasgow.

LASGOW EYE INFIRMARY, Berkeley-street and rlotte-street.—The wards and dispensary are gnised by the University of Glasgow for the purpose instruction in ophthalmology for graduation in dicine, and by the Royal Colleges of Physicians and geons of England for the Diploma in Ophthalmic dicine and Surgery. A Venereal Centre has been blished, and a Branch Dispensary has been opened Clydebank. Post-graduate Classes are held. retary and Acting Treasurer, Mr. Harold John ck, 171, West Regent-street, Glasgow.

LASGOW EAR, NOSE, AND THROAT HOSPITAL, , St. Vincent-street (48 beds).—At out-patient l in-door departments clinical instruction is given. st-Graduate Courses are held during the year. retary: D. N. Mackay, 144, St. Vincent-street, sgow.

NIVERSITY OF ST. ANDREWS (UNITED COLLEGE ST. ANDREWS AND UNIVERSITY COLLEGE, DUNDEE).

our Degrees in Medicine and Surgery are conferred the University of St. Andrews—viz., *M.B.*, *Ch.B.*, *D.*, *Ch.M.*, a Diploma in Public Health, and Diploma Dental Surgery (*L.D.S.*).

he Preliminary Examination is either the Arts the Pure Science Preliminary Examination. The s Preliminary includes English, Latin or Greek, l Mathematics, and a fourth subject which may a foreign language or Dynamics. In the Science liminary Examination French or German may be stituted for Latin or Greek and Mathematics must on the higher standard. Otherwise the subjects the same as the Arts Preliminary Examination. legree in Arts or in Science in any of the Universities he United Kingdom and in some colonial and foreign versities exempts. The Preliminary Examina- n for graduation in Medicine and Surgery, Arts or ence, of the University of St. Andrews is accepted equivalent to the Registration Examination required the General Medical Council (the certificate to lude the required subjects). Also the Final amination for a degree in Arts or Science and the al Examination for the Diploma of L.L.A.

Degrees of Bachelor of Medicine and Bachelor of rgery.—A pre-registration examination is held in ysics and Chemistry. Candidates must have been gaged in medical study for at least five years after istering as a medical student. In each of the st four years the candidate must have attended at st two courses of instruction in one or more of the bjects of study specified below, each course extending er a session of not less than five months, either continuous or divided into two terms, or, alternatively, one such course along with two courses, each extending over a session of not less than two and a half months. During the fifth or final year the candidate shall be engaged in clinical study for at least nine months at the Infirmary of Dundee or at one or more of such public hospitals or dispensaries, British or foreign, as may be recognised for the purpose by the University Court. The candidate must have received instruction in each of the following subjects of study, including such examinations as may be prescribed in the various classes—viz., Anatomy, Practical Anatomy, Chemistry, Materia Medica, Physiology, or Institutes of Medicine, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Infants, Pathology, Bacteriology, Practical Chemistry, Physics, Elementary Botany, Elementary Zoology, Practical Physiology, Practical Pathology, Forensic Medicine, and Public Health. The candidate must have attended for at least three years the Medical and Surgical Practice either of the Infirmary of Dundee or of a General Hospital elsewhere with not fewer than 80 patients, with a distinct staff of physicians and surgeons, and recognised for the purpose by the University Court. Additional subjects of study are Practical Pharmacy, Mental Diseases, Practical Midwifery, Operative Surgery, Vaccination, Children's Diseases, Fevers, Ophthalmology, Diseases of the Ear, Throat, and Nose, Anæsthetics, Dermatology and Post-mortem Examinations.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations shall have effect:—1. Two of the five years of medical study must be spent in the University of St. Andrews. 2. The remaining three years may be spent in any University of the United Kingdom or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. Women are admitted to graduation in Medicine, subject to certain provisions.

Professional Examinations for the Degrees of Bachelor of Medicine and Bachelor of Surgery.—Each candidate will be examined both in writing and orally, and also clinically where the nature of the subject admits, in the following divisions—viz., first, in Botany, Zoology, Physics, and Chemistry; second, in Anatomy and Physiology; third, in Materia Medica, Pathology and Bacteriology, Forensic Medicine and Public Health; and fourth, in Surgery, Clinical and Operative Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and Gynæcology (Systematic and Clinical).

UNIVERSITY COLLEGE, Dundee.—This College is one of the constituent colleges of the University of St. Andrews. In the Conjoint Medical School there are spacious and well-equipped laboratories. The complete medical curriculum can be taken in Dundee, beginning in University College (first two years) and continuing in the Conjoint Medical School.

ROYAL INFIRMARY, Dundee (461 beds).—In addition to the ordinary Medical and Surgical Wards, there are special departments for Midwifery (In- and Out-door), for Diseases of Women, of Children, of the Eye, of the Ear, Nose, and Throat, and of the Skin; and for Clinical Pathology, Radiology, Electrotherapeusis, and Electrocardiography. An extension providing for a new X Ray Department and Massage Department and for additional Operation Theatre accommodation has been opened recently, and a new Maternity Department is being built at a cost of £32,000. Clinical teaching is given to male and female students by the Honorary Staff; post-mortem examinations are conducted by the pathologists. All courses of instruction are recognised by the University of St. Andrews and the other Boards of the United Kingdom. Nine Resident Medical Officers are appointed every six months. Clinical clerks and dressers are attached to the

Physicians and Surgeons; and Students are appointed as assistants in the pathological department. Further information may be obtained from the Medical Superintendent.

UNIVERSITY OF ABERDEEN.

The University of Aberdeen grants four degrees in Medicine and Surgery—viz., *M.D.*, *Ch.M.*, *M.B.*, and *Ch.B.* The Degree of Doctor of Philosophy (*Ph.D.*) is also granted in the Faculty of Medicine.

Degrees of M.B. and Ch.B.—Candidates, before entering on the curriculum, must have passed the Preliminary Examination or hold a qualification recognised as exempting from such examination, have attained the age of 17, and have passed the Pre-registration Examination in Physics and Chemistry.

The curriculum for the degrees extends over a period of five years, during which attendance is required in the following subjects: Botany, Zoology, Physics, Chemistry (Systematic and Practical), Anatomy (Systematic and Practical), Physiology (Systematic and Practical), Materia Medica and Therapeutics, Practical Pharmacy, Pathology (Systematic and Practical), Medical Jurisprudence, Public Health, Surgery, Medicine, and Midwifery.

Candidates must attend for at least three years the medical and surgical practice of a recognised hospital; they must have attended courses of at least nine months in clinical medicine and clinical surgery, and have acted as clerk in the medical and dresser in the surgical wards of a hospital. Attendance is required on the practice of a dispensary or the out-practice of a hospital and also on courses in Mental Diseases, Fevers, Ophthalmology, Post-mortem Examinations, Venereal Diseases, Tuberculosis, and other special subjects. The candidate is also required to have been properly instructed in Vaccination and to have attended at least 20 Midwifery cases.

Degrees of M.D. and Ch.M.—Candidates for either of these degrees must already hold the degrees of M.B. and Ch.B. of Aberdeen. A thesis (in duplicate) has to be presented and an examination has to be passed in Clinical Medicine (or in some special Department of Medical Science) or Clinical Surgery, as the case may be.

Degree of Ph.D.—For this degree candidates must pursue a course of special study or research during a period of nine academical terms as Research Students in the University of Aberdeen or in any College or Institution that may be affiliated thereto. A Thesis (in duplicate) must be presented for approval.

A diploma in Public Health is granted by the University to graduates in Medicine of a University in the United Kingdom, after a special examination.

Scholarships and Prizes.—In the Faculty of Medicine of the University of Aberdeen there are the following Bursaries, Scholarships, and Prizes:—Bursaries: about 15 Bursaries (competition and presentation) are open each year, of £15 to £30 per annum in value, most of them being tenable for three years. Scholarships: five Post-Graduate Scholarships, value £36 to £160 per annum. Prizes and Medals: 15 Gold Medals and Prizes for proficiency in special departments.

ABERDEEN ROYAL INFIRMARY (335 beds).—The main clinical work of the students is done in the Infirmary with its general and special facilities. A Department of Clinical Chemistry has recently been instituted by the physicians and surgeons on the staff; and, besides the RoyalInfirmary, students have the opportunity of attending the following institutions: City Fever Hospital, Sick Children's Hospital, General Dispensary and Lying-in and Vaccine Institutions, Royal Lunatic Asylum, Ophthalmic Institutions, and the Aberdeen Royal Mental Hospital. This hospital contains, with hospital attached to main institution and agricultural branch, about 950 beds. Clinical instruction is given to students during three months in summer. Physician-Superintendent, Dr. R. Dods Brown.

SCOTTISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

These Colleges have made arrangements by whi after one series of examinations, held in Edinburgh Glasgow, or both, the student may obtain the diplom of the three bodies. This is the Scottish Conjoi Board.

The three bodies grant their Single Licences only candidates who already possess legal qualifications Medicine or Surgery.

The hospitals which are recognised by the Scotti Conjoint Board as places where professional study i their diplomas can be pursued are all those institutio which feed the medical faculties of the universiti as well as all the places which are recognised the English and Irish Conjoint Boards.

Professional Education.—The candidate must p duce certificates or other satisfactory evidence having attended the following separate and disti courses of instruction: Physics, three mont Elementary Biology, three months; Chemistry, months; Practical or Analytical Chemistry, th months; Anatomy, during at least six mont Practical Anatomy, twelve months; Physiolo six months; Practical Physiology, three mont Materia Medica, three months; Pathology (includi Practical Pathology), nine months; Practice Medicine, six months; Clinical Medicine, nine mont Principles and Practice of Surgery, six mont Clinical Surgery, nine months; Midwifery, th months; Gynæcology, one course of not less than meetings; Diseases of Children, one course of not l than 13 meetings; Medical Jurisprudence and Pu Health, three months. The certified attendance lectures, demonstrations, and practical work must n be less than three-fourths of the total number roll-calls. Every student undergoes a course Practical Midwifery, but before attending at labo he is required to attend a course of lectures on Surg and Midwifery and to hold the offices of Clini Medical Clerk and Surgical Dresser. He must a attend for two and a half months instruction Practical Pharmacy; the certificate to be signed the teacher, who must be a member of the Pharm ceutical Society of Great Britain, or the superintend of the laboratory of a public hospital or dispensary, a registered practitioner who dispenses medicines his patients, or a teacher of Practical Pharmacy.

The student must attend for 27 months the Medi and Surgical practice of a public general hospi containing on an average at least 80 patients availa for clinical instruction, and possessing distinct staffs physicians and of surgeons. He must act as Surgi Dresser and Medical Clinical Clerk for not less th six months in the wards in each case, and rece practical instruction in administration of anæstheti He must attend for six months the practice of public dispensary especially recognised by any of t above authorities, or the out-patient practice of recognised general hospital. This attendance shou be made after the student has passed the First a Second examinations.

Candidates are also required to attend the followi courses: Diseases and Injuries of the Eye, th months; Insanity, three months; Infectious Diseas three months; Gynæcology, three months; Disea of Children, three months.

The curriculum lasts for five years, the fifth ye being devoted to clinical work.

There are four professional examinations:—

First Examination includes Physics, Chemistry, a Elementary Biology.

Second Examination includes Anatomy and Phys logy and Histology; and candidates may be admitt

this examination at the end of the second year of dical study.

Third Examination includes Pathology and Materia dica with Pharmacology.

Final Examination.—The Final Examination shall be taken earlier than the end of the fifth year of dy and shall embrace the following subjects:—dicine, including Therapeutics, Medical Anatomy, d Clinical Medicine; Surgery, including Surgical atomy, Clinical Surgery, and Diseases and Injuries the Eye; Midwifery and Diseases of Women; and, not passed previously, Medical Jurisprudence and blic Health; but it is optional to candidates who ve passed the Third Examination to be admitted the subject of Medical Jurisprudence and Public alth on lodging certificates of having attended the cessary course in that subject at any time; but subjects of Medicine, Surgery, and Midwifery shall taken together at any time after the end of the h Winter Session, provided that a period of 24 nths has elapsed since passing the Second Examina-n. All candidates shall be subjected, in addition the written and oral examinations, to clinical aminations in Medicine and Surgery, which shall lude the Examination of Patients, Physical agnosis, the Clinical Use of the Microscope, Examina-n of the Urine and Urinary Deposits, Surgical pliances, Bandages, and Surface Markings.

There are four periods of examination annually. The Registrar in Edinburgh is Mr. D. L. Eadie, Lauriston-place; and the Registrar in Glasgow, . Walter Hurst, 242, St. Vincent-street, to whom s and certificates must be sent for the respective aminations, and from whom particulars of fees can obtained.

For students registered with the General Medical uncil after Jan. 1st, 1923, more extensive Regula-ns are in force, and candidates applying for Regu-ions should state date of registration.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

In addition to the diplomas granted by the Scottish njoint Board the Royal College of Physicians ants its Single Licence to candidates already ssessing legal qualifications for professional practice.

The Royal College of Physicians of Edinburgh ants a *Membership* and a *Fellowship*.

Membership.—A candidate, who must be a Licen-te of a British or Irish College of Physicians, or a aduate in medicine of a University, approved by e Council, and 24 years of age, is examined in edicine, therapeutics, and in any branch of the partments of medicine specially professed, such general pathology, psychology, public health stetrics, gynæcology, diseases of children, tropical edicine, or medical jurisprudence.

Fellowship.—The Fellows are selected from the nks of the *Members*.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

The Royal College of Surgeons of Edinburgh lmits to the examination for its Single Licence any ndidates who hold a Diploma in Medicine of any ritish, Indian, or Foreign university or of any ritish College of Physicians, or of the Society of pothecaries of London or Apothecaries' Hall, ublin, granted under the provisions of the Medical ct, 1886, whose preliminary examination and course professional study is proved to be sufficient to lfil the requirements of the College, or to those who ve passed a full examination for any of the above. emale practitioners are admitted to the Licence the College and also to the Fellowship, and the gulations apply to practitioners of either sex.

The College grants a diploma of Fellowship after xamination to the holders of British surgical degrees r diplomas and the holders of recognised degrees of the Universities of Canada, Australia, New Zealand, and the Indian Empire.

The Fellowship.—Candidates must be 25 years of age and in practice for at least two years. The examination is written and viva voce, and includes surgery and surgical anatomy, operative surgery, and clinical practice. One optional subject must also be taken, the range of these specialisms covering nearly every branch of medicine. Candidates are not allowed to appear for more than three times at the examinations. One month's notice of intention to appear for examination must be given by the candidate to the College, together with credentials, signed by two Fellows, one a resident in Edinburgh, or six testimonials, to the President and Council.

THE ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

The Royal Faculty of Physicians and Surgeons of Glasgow grants a Fellowship and a Licence to be held separately. The Licence is granted as a separate qualification to qualified practitioners in Medicine after examination in surgery, including surgical anatomy and clinical surgery.

Fellowship.—The Fellowship of the Faculty is granted after examination in medicine or surgery, together with an optional subject, which may be anatomy or physiology or be selected from any special branch of medicine or surgery. Fourteen days' notice must be given by the candidate to the Faculty. In certain circumstances Fellows may be elected as a mark of distinction.

III.—IRELAND.

THE UNIVERSITIES.

UNIVERSITY OF DUBLIN, TRINITY COLLEGE (SCHOOL OF PHYSIC).

Matriculation.—University students take the Entrance of Trinity College and a Junior Freshman Term or a special Medical Preliminary; Extern Students, any examination recognised by the General Medical Council.

Pre-registration Examination in Elementary Physics and Chemistry.—Before beginning the five years' Medical curriculum students must pass an examination in elementary Physics and Chemistry. This examination is held at the end of September, in January, in March, and in June. Courses in preparation for it may be taken in the School of Physic.

Degrees in Medicine (M.B.), Surgery (B.Ch.), and Midwifery (B.A.O.).—Candidates for these degrees must be of B.A. standing and must be for at least five academic years on the books of the Medical School, reckoned from the date of registration. The Arts course may be taken concurrently with the Medical course, and the B.A. degree need not be taken before the final medical examinations, but the Medical degrees are not conferred without the Arts degree. The following courses must be attended:—(1) Lectures—Botany, Zoology, Physics and Practical Physics; Systematic, Descriptive and Applied Anatomy; Chemistry and Practical Chemistry; Histology, Physiology, Practical and Applied Physiology; Practice of Medicine; Midwifery and Gynæcology, Pathology and Bacteriology; Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene; Surgery and Operative Surgery; (2) three courses of nine months' attendance on the Clinical Lectures of Sir Patrick Dun's or other recognised Hospital; (3) Practical Vaccination, one month's instruction; (4) Mental Disease, three months; (5) Practical Midwifery with Clinical Lectures, including not less than 20 personally conducted cases, six months; (6) Ophthalmic Surgery, three months. Three groups of examinations have to be passed. Preliminary Scientific Examination, including Physics and Chemistry, Botany, and Zoology. The Intermediate Medical, Part I., including Anatomy, Physiology, and Organic Chemistry; and Part II.,

including Applied Anatomy and Applied Physiology; and the Final Examination, which is divided into Part I., Materia Medica and Therapeutics, Hygiene and Jurisprudence, Pathology and Bacteriology; and Part II., Medicine, including Clinical Medicine and Mental Diseases; Surgery, including Operative and Ophthalmic Surgery; Midwifery and Gynæcology. Part I. may be passed in the fourth year and Part II. completed at the end of the fifth.

Doctor in Medicine.—A Doctor in Medicine must have passed all the qualifying examinations and must be a B.A. of three years' standing. He must also submit a thesis and pass an Examination before the Regius Professor of Physic.

Master in Surgery.—A Master in Surgery must be a Bachelor in Surgery of the University of Dublin of not less than three years' standing, and must produce satisfactory evidence of having been engaged for not less than two years from the date of his registration in the study, or study and practice, of his profession. He must then pass a special examination.

Master in Obstetric Science.—A Master in Obstetric Science must be a Bachelor in Obstetric Science of two years' standing, and must produce evidence of having been engaged in the study of Obstetric Medicine and Surgery during two years. He is then required to pass a special examination.

Diploma in Gynæcology and Obstetrics.—A post-graduate diploma is conferred upon registered medical practitioners who take a six months' course at the Rotunda Hospital or other recognised institution, a six months' course in Trinity College, and then pass a special examination. The minimum time required for the complete course is nine months.

Bachelor in Dental Science and Master in Dental Science.—The regulations under which these degrees are awarded can be obtained by application to the Registrar of the School of Physic.

All Degrees and Courses of Instruction are open to women students.

Post-graduate Instruction.—Arrangements have been made, with the approval of the Board of Trinity College, for a post-graduate course of instruction at the School of Physic during the autumn from Monday, Sept. 12th, to Saturday, Oct. 1st. Members of the class can reside in college rooms and dine on commons.

Clinical Instruction.—The hospital facilities for clinical instruction available in Dublin will be described below.

NATIONAL UNIVERSITY OF IRELAND.

Matriculation.—All students must pass a matriculation examination; the examination taking place in June and September in Dublin, and at certain local centres, includes five subjects, three of which must be Irish, English, and mathematics. All students must pass in Irish except students not born in Ireland, and other students whose home residence shall have been outside Ireland during the three years immediately preceding their matriculation; but all such students will be expected to attend a course of instruction in Irish Literature and History prior to obtaining any degree in the University. The following are the subjects for examination:—1. Irish. 2. Latin or Greek. 3. French, German, Italian, Spanish, Portuguese, Welsh, or any other modern language approved by the Senate. 4. English. 5. Mathematics. 6. Latin, Greek, French, German, Welsh, Spanish, Italian, Portuguese, or any other modern language approved by the Senate, History, Geography, Applied Mathematics, or Physics as an alternative, Chemistry, Botany, Agricultural Science, Commerce, Music, and for women candidates only Physiology and Hygiene. Students entering for degrees in Medicine or Dentistry, if already registered by the General Medical Council, must take Irish, Latin, English, Mathematics, and a fifth subject.

The medical degrees granted are:—

M.B., B.Ch., and B.A.O.; and M.D., M.Ch., and M.A.O., Ph.D.—Printed forms of application for admission to any medical examination may be h from "The Registrar, The National University Ireland, Dublin."

The Constituent Colleges of the National Universi of Ireland at which the full curriculum for medi degrees can be obtained are University Colle Dublin; University College, Cork; and Universi College, Galway.

UNIVERSITY COLLEGE, DUBLIN.—*Matriculation.* Almost all the students of the College a matriculated students of the National Universi of Ireland. The pre-registration examination physics and chemistry is taken after matriculati either at the beginning of or during the win session. The course is of five years' duration and da from the passing of the pre-registration examinati

Degrees of M.B., B.Ch., and B.A.O.—The Fi Examination includes Applied Physics, Appli Chemistry, Botany, Zoology, and Applied Biolo The examination may be taken in two part Part I., Physics and Chemistry; Part II., Bota and Zoology. Honours may be obtained o when both parts are taken as one examination. T Second Examination includes Anatomy and Phys logy. Both must be passed at the same time. T Third Examination includes Pathology, Medi Jurisprudence and Hygiene, and Materia Medi The Fourth examination includes Hygiene a Medical Jurisprudence.

The Examination in Medicine, Midwifery, Surge and Ophthalmology includes both the theoretical a the clinical branches. No student can enter for t M.B., B.Ch., or B.A.O. until the end of the fifth y when the curriculum has been completed. T degree of M.D. may be obtained either by examinati or on published work.

UNIVERSITY COLLEGE, CORK: THE SCHOOL MEDICINE.—Students must have passed the Matricu tion Examination of the University or some otl recognised examination, and a preliminary exami tion recognised by the General Medical Council.

Medical Students who have passed the Fi Professional Examination of the Conjoint Boa of Ireland, England, or Scotland may be admitt to the rank of second-year students on mak application to the Council. Similarly, students w have passed the Second Professional Examinat of the same Boards may be admitted to the rank third-year students; and those who have pass the Third Professional Examination of the Dub Colleges, or of the Edinburgh Colleges and Glasg Faculties, may rank as fourth-year.

The school is provided with physiologi toxicological, pathological, and pharmaceuti laboratories, materia medica, anatomical and pat logical museums, as well as a collection of surgi and obstetrical instruments and appliances. Th are dissecting-rooms, well-appointed physical, che cal, and biological laboratories, a large natu history museum in the adjoining building, and part the College ground is laid out as a botanical gard The plant houses are well filled with plants and open to the students in the class of Botany. T Library contains about 70,000 volumes and is op daily during term time to students. The Medi Museum occupies a large room erected at northern end of the medical buildings. There Students' Clubs for men and women students of College and various athletic clubs.

Residence of Students.—Students not living home, or with relatives or friends, sanctioned their parents or guardians, are required to live a hostel or in recognised lodgings, and register th addresses each session. The Honan Hostel, adjoin the College, is equipped by private endowme A number of sets of rooms, together with recreat and common rooms, are provided for lay stude who may desire to live there. For full particul apply to the Warden. The Ursuline Convent, Bla rock, has a house of residence, quite separate fr their Secondary School, for Catholic women stude

Clinical Instruction.—Students may attend the South Charitable Infirmary and County of Cork General Hospital, Cork North Charitable Infirmary and City of Cork General Hospital, the Mercy Hospital, the Cork District Lunatic Asylum, the Victoria Hospital for Diseases of Women and Children, the County Lying-in Hospital, the Cork Maternity, Fever, the District, and Ear, Eye, and Throat Hospitals.

Complete information with regard to class fees, scholarships, and prizes can be obtained from the Dean of the Medical Faculty, and in respect of the hospitals from the Secretaries.

UNIVERSITY COLLEGE, GALWAY: SCHOOL OF MEDICINE.—The College contains a well-lighted and ventilated dissecting room and an anatomical lecture theatre; physiological, pathological, pharmaceutical, chemical, and physical laboratories; anatomical, pathological, gynæcological, and materia medica museums; as well as large natural history and geological museums and an extensive library in which students can read and from which they can borrow books. There are 12 Entrance Scholarships, value £25 each, for which Medical Students compete with other students on the Entrance Course. In the Second, Third, and Fourth years three Scholarships in each year, value £25 each, are reserved for Medical Students. The H. H. Stewart Scholarships (£10 a year for three years) are awarded by the University in Anatomy and Physiology at Second Medical Examination amongst students of the three constituent Colleges. Travelling Studentships (£200 a year for two years) are offered by the University for competition amongst Medical Graduates of the three Colleges of not more than two years' standing. Women students are eligible for all College and University Degrees, Distinctions, and Prizes. There are extensive grounds, a portion of which is occupied by a Botanic Garden and a portion is at the disposal of the College Athletic Union. There are several student societies in the College, including a Biological Society. There are abundant facilities for research and Post-graduate work in the Chemistry, Physiology, and Pathology departments. There are ample facilities for Women Students. Further information can be obtained from the Registrar of the College.

Clinical Instruction is given in the Galway Tuberculosis Hospital and in the Galway Central and Fever Hospitals, containing on an average 350 patients.

CENTRAL HOSPITAL, GALWAY (300 beds).—In this completely renovated hospital, in addition to the Finer Surgical and Medical Departments, there are now Eye and Ear, Throat and Nose, Gynæcological and Obstetrical, Pathological, X Ray, Ultra-Violet Rays, and Electrical and Massage Departments. Students attend from University College, Galway. Medical and Surgical Clinics are held on alternate days during term. One Resident Physician and one Resident Surgeon are appointed every six months. The hospital is open to qualified medical men for post-graduate work.

QUEEN'S UNIVERSITY OF BELFAST.

There are six degrees in the Faculty of Medicine of the University—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (B.Ch.), Bachelor of Obstetrics (B.A.O.), Doctor of Medicine (M.D.), Master of Surgery (M.Ch.), and Master of Obstetrics (M.A.O.). The University also grants a Diploma in Public Health, particulars of which will be found in the University Calendar. The degrees of M.B., B.Ch., and B.A.O. are the primary degrees in the Faculty of Medicine, and are conferred at the same time and after the same course of study. No student is admitted to the final examination for these degrees until he has shown: (1) that he is a matriculated student of the University; (2) that he has completed the prescribed course of study in the Faculty of Medicine extending over a period of not less than five academic years from the date of his registration as a student of Medicine; (3) that he has passed the several examinations prescribed; (4) that he has attended in the University during three academic years at least the courses of study prescribed for such degrees (the Senate may accept, for not more than two academic years of the required five, courses of study pursued in any other University or School of Medicine approved by the Senate); and (5) that he has attained the age of 21 years. Every candidate for admission shall matriculate or fulfil such other test of fitness as may be prescribed by the Senate, or may be exempted from the matriculation examination by having passed similar examinations elsewhere. For information as to Scholarships and Prizes inquiry should be made of the Secretary of the University.

Primary Degrees of M.B., B.Ch., B.A.O.—All candidates for these degrees must satisfy the examiners in the subjects of four examinations.

The First Medical Examination.—The subjects of this examination are Chemistry (Inorganic and Organic), Experimental Physics, Botany and Zoology. The examination will be divided into two parts which may be taken separately: I., Chemistry and Physics; II., Botany and Zoology.

The Second Medical Examination.—The subjects are Anatomy and Practical Anatomy, Physiology and Practical Physiology. Candidates who have previously passed the First Medical Examination may present themselves for this examination at the close of their second year.

The Third Medical Examination.—The subjects are: (1) Pathology and Practical Pathology; (2) Materia Medica, Pharmacology and Therapeutics; (3) Medical Jurisprudence; (4) Hygiene. Candidates who have previously passed the Second Medical Examination may present themselves for this examination at the close of the third year. Attendance on a course in any subject of the Third Medical Examination shall not entitle a student to a certificate of attendance unless he has previously passed in all the subjects of the Second Medical Examination.

The Fourth Medical Examination.—The subjects are: (1) Medicine; (2) Surgery; (3) Midwifery; (4) Ophthalmology and Otology. This examination may be taken in two parts: I., Systematic; II., Clinical, Practical and Oral. Candidates who have previously passed the Third Examination may present themselves for Part I. of the Fourth Examination at the close of the fourth year, provided that they have fulfilled the necessary requirements as to attendance, &c., on the courses of instruction in the subjects of examination. Candidates who have passed Part I. of this examination may present themselves for Part II. at the close of the fifth year, provided that they have fulfilled the necessary requirements as to hospital attendance on the various clinical courses in the subjects of examination. Parts I. and II. may be taken together at the close of the fifth year. Attendance on a course in any subject of the Fourth Medical Examination shall not entitle a student to a certificate of attendance unless he has passed in the subjects of the Second Medical Examination.

Degrees of M.D., M.Ch., and M.A.O.—These degrees are not conferred until the expiration of at least three academic years, or in the case of graduates of the University in Arts or Science of at least two academic years, after admission to the primary degrees in the Faculty of Medicine. Every candidate must show that in the interval he has pursued such courses of study, or been engaged in such practical work as may be prescribed. These degrees may be conferred by the Senate either (*a*) after an examination, which includes written, oral, clinical, and practical examinations; or (*b*) on the submission of a thesis or other evidence of original study or research, to be approved by the Faculty of Medicine after an oral or other examination of the candidate on the subject.

The Medical School.—The Donald Currie Chemical Buildings contain a lecture theatre, a preparation room, a chemical museum, a large class-room for

elementary practical chemistry, laboratories for qualitative and quantitative analysis, rooms for water and gas analysis, dark room for photographic purposes and balance room, provided with all modern appliances. The Anatomical Department contains a large and well-lighted dissecting-room, a lecture-room, a professor's and demonstrator's room, a bone-room, and a laboratory for microscopic and photographic work. The Medical Museum is in the same building. The Jaffé Laboratories for Physiology comprise a lecture theatre, laboratories for practical work in chemical physiology, histology, and experimental physiology, and in addition small private research rooms, including balance, galvanometer, and centrifuge rooms. The J. C. White laboratories, recently founded, are fully equipped for research in biochemistry and bacteriology. The Musgrave Pathological Laboratory.—In this department opportunity is afforded for research in pathology and bacteriology. The department is in touch with most of the hospitals in Belfast, and there is an ample supply of material for investigation by graduates in morbid histology, clinical pathology, and the bacteriology of infectious diseases. A course in pathology or bacteriology is given to graduates, and members of this class have an opportunity of seeing the methods employed in the various investigations carried out in the department for the Public Health Committee of the corporation in connexion with water-supply, sewage disposal, meat- and milk-supply, the diagnosis of cases of infectious diseases, &c. The certificate issued to members of the class in bacteriology qualifies for the D.P.H. degree. The Pharmaceutical Laboratory is fitted and equipped for the work of practically instructing students in the compounding and dispensing of medicines.

Clinical Instruction.—The following institutions are recognised by the University as affording proper opportunities for clinical instruction: the Royal Victoria Hospital, the Mater Infirmorum Hospital, the Union Hospitals, the Belfast Hospital for Sick Children, the Belfast Maternity, the Ulster Hospital for Women and Children, the Ulster Eye, Ear, and Throat Hospital, the Belfast Ophthalmic Hospital, the Purdysburn Fever Hospital, and the Belfast District Lunatic Asylum. Complete information can be obtained from the respective Secretaries.

ROYAL VICTORIA HOSPITAL, BELFAST, 436 beds.—Students eligible for McGrath, McQuitty, Malcolm, Coulter Smyth and Elwood Scholarships aggregate annual value £185. Twelve House Surgeons and House Physicians. Thirty-six resident pupilships, three months each, annually for Senior Students, of which a proportion is allotted to Women Students, Special Departments for Radiology, Clinical Pathology, V.D., Dermatology, Gynæcology, Vaccine Therapy, Electrocardiography, Dentistry.

MATER INFIRMORUM HOSPITAL, BELFAST.—This hospital contains 270 beds and is open at all hours for the reception of accidents and urgent cases. Clinical instruction is given daily by Physicians and Surgeons. Surgical operations are performed daily. The out-patient departments in Medicine and Surgery, also the special dispensaries for Gynæcology, Ear, Eye and Throat, Electrotherapeutics, Venereal Diseases are very largely attended and afford valuable opportunities to students for the study of those subjects. A House Physician and two House Surgeons are elected every six months. Resident pupils are admitted as the vacancies arise. Three Exhibitions and a Gold Medal are competed for annually in June. Certificates of attendance upon this hospital are recognised by all the Universities and licensing bodies in the United Kingdom.

BELFAST INFIRMARY AND HOSPITAL (1600 beds).—Clinical courses are given quarterly, and a course for D.P.H. in Hospital. Intern Venereal Clinic in Infirmary under Corporation scheme. Maternity Hospital recognised for Practical Midwifery training. Particulars may be obtained on application to the Hon. Sec. Visiting Medical Staff. Certificate of vaccination class recognised by Local Government Board. A new department for Cancer with 32 beds has been opened.

THE BELFAST HOSPITAL FOR SICK CHILDREN, Queen-street (45 beds).—Clinical instruction is given in this hospital. During the Winter Session two Courses of Lectures are delivered on the Medical and Surgical Diseases incidental to Infancy and Childhood. Demonstrations in Ophthalmology and Pathology are given and ample opportunities are afforded in the wards and in the Out-patient Department for gaining a practical and theoretical knowledge of the diseases of Infancy and Childhood. This Hospital grants Certificates in Diseases of Children, which are recognised by the various Examining Bodies. A Gold Medal is offered for competition at the close of the session.

MATERNITY HOSPITAL, Townsend-street, Belfast.—Twenty-five beds in constant occupation, and exclusively devoted to Midwifery and Antenatal conditions. There is also a large district. The Queen's University of Belfast have erected a Students' Hostel in connexion with the Hospital where six Students and Post-graduates are received each month. The University Tutor in Obstetrics resides in the Hostel and Students conduct their cases under his supervision. There is a large Antenatal Department and a Department for Venereal Diseases. Communications should be made to C. H. G. Macafee, M.B., Hon. Secretary of the Medical Staff.

ULSTER HOSPITAL FOR CHILDREN AND WOMEN, Templemore-avenue, Belfast (56 beds).—Clinical instruction to students in Diseases of Children, Gynæcology and Obstetrics. Special departments: Radiology and Actino-therapy, Eye, Ear, and Throat, V.D. Clinic and Antenatal Clinic. Gold Medal awarded annually. Two House Surgeons appointed from students of hospital.

BENN ULSTER EYE, EAR AND THROAT HOSPITAL, Clifton-street, 30 beds, and BELFAST OPHTHALMIC HOSPITAL, Great Victoria-street, 30 beds.—Practical demonstrations by the staff and occasional clinical lectures in the subjects of Ophthalmology, Otology and Laryngology. Clinical instruction is given daily.

BELFAST FEVER HOSPITALS.—City Fever Hospital, Purdysburn (360 beds); Union Fever Hospital (200 beds). Clinical Classes are held during the winter and summer sessions. Post-Graduate (D.P.H.) Classes are also held.

BELFAST MENTAL HOSPITAL (PURDYSBURN VILLA COLONY) (1100 beds). University Lectures and clinics.

IRISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND AND ROYAL COLLEGE OF SURGEONS IN IRELAND.

The Irish Conjoint Board requires of candidates the passage either of its own preliminary examination in the subjects of general education or proof that the candidate has passed one of the tests accepted by the General Medical Council as well as passing in the Pre-Registration Examinations in Chemistry and Physics and Biology.

Professional Examinations.—There are three professional examinations, the first of which cannot be passed earlier than the end of the second winter session, nor the final before the conclusion of full five years of medical study. Before being admitted to any of them the candidate must show that he has studied the different subjects in practice and theory for the requisite periods, certificates to this effect being accepted from the authorities of most of the

cognised medical schools at home and abroad. he first examination deals with (*a*) Anatomy, id (*b*) Physiology and Histology. The second xamination deals with (*a*) Pathology, (*b*) Materia edica, Pharmacy, and Therapeutics and Ophthalmo-gy, and may be taken separately.

Final Examination.—This is divided into three visions, which cannot be completed until at least ve years have passed in medical studies other than ose for the Pre-Registration Examinations, and ve years at least since the beginning of the curri-lum. The divisions are (*a*) Medicine, including evers, Mental Diseases, and Diseases of Children;) Surgery, including Operative Surgery; (*c*) Mid-ifery, including Diseases of Women and Children, id the Practice of Vaccination.

Diploma in Psychological Medicine.—There are two aminations in connexion with this Diploma: art I. consists of (*a*) Anatomy and Physiology of the ervous System; (*b*) Psychology. Part II.: (*a*) eurology, including Clinical and Pathological Neuro-gy; (*b*) Psychological Medicine, including its legal lationships.

Further information can be obtained from the cretary of the Committee of Management, Royal llege of Surgeons, St. Stephen's Green.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

The College issues its Licences in Medicine and in dwifery to practitioners whose names appear on the edical Register of the United Kingdom.

The Licence in Medicine.—The subjects of examina-n are: Practice of Medicine, Clinical Medicine, thology, Medical Jurisprudence, Midwifery, Hygiene, d Therapeutics.

The Licence in Midwifery.—Candidates must pro-ce certificates of registration. A registered medical actitioner of five years' standing may be exempted m the examination by printed questions.

The Membership.—Examinations for Membership held in February, June, and November.

The Fellowship.—Fellows are elected by ballot. pplicants must have been a Member of the College at least one year and must have attained the age 27 years.

Further particulars can be obtained from the gistrar of the Royal College of Physicians of land, 6, Kildare-street, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The College issues its Licence in Surgery to actitioners whose names are entered either on the edical Register for the United Kingdom, the Colonial edical Register, or the Foreign Medical Register the year in which he presents himself for examina-n, and who satisfies the Council that he has passed rough a course of study and Examinations equiva-nt to those required by the Regulations of the Irish njoint Board.

Candidates are examined in General Surgery aper and oral), Clinical Surgery, Surgical Pathology ral), Operative Surgery, Surgical Anatomy (paper), d Ophthalmic and Aural Surgery (clinical).

Diploma in Midwifery.—A diploma in Midwifery is anted after examination to persons possessing a gistrable qualification.

Fellowship Examinations.—Candidates for the Fel-wship shall make application to the President and uncil to be admitted to examination. They are quired to pass two examinations—Primary and nal. Candidates may present themselves for the nal Examination immediately after passing the imary part, provided they have complied with the necessary regulations. The subjects for the Primary Examination are (*a*) Anatomy, including Dissections; and (*b*) Physiology and Histology. The subjects for the Final Examination are Surgery, including Surgical Anatomy and Pathology. For admission to the Final Examination the candidate must have passed the Primary Examination, and must be a Licentiate or Graduate in Surgery of a university or licensing body recognised by the General Medical Council; all such candidates must not be less than 25 years of age.

Further particulars can be obtained from the Registrar of the College, Stephen's-green West, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND (SCHOOLS OF SURGERY).—The schools of surgery are attached by Charter to the Royal College of Surgeons and have existed as a department of the College for over a century. They are carried on within the College buildings and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the professors and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting-room nearly trebled, and special pathological, bacteriological, public health, and pharmaceutical laboratories fitted with the most approved appliances in order that students may have the advantage of the most modern methods of instruction. The entire building is heated by hot-water pipes and lighted throughout by the electric light. Winter Session commences in October; Summer Session in April. Scholarships and Prizes: Carmichael Scholarship, £15; Mayne Scholarship, £8; Stoney Memorial gold medal; Operative Surgery, gold and silver medals; Barker Prize, £26 5*s.*; H. Macnaughton-Jones gold medal in Obstetrics and Gynæcology; and class prizes and medals. Prospectuses and guide for medical students can be obtained post free on written application to the Registrar, Royal College of Surgeons, Stephen's-green W., Dublin.

APOTHECARIES' HALL OF IRELAND.

The Licence of this Hall is granted to students who present certificates of having fully completed the course of study as laid down in the curriculum and who pass the necessary examinations. The diploma of the Hall entitles the holder to be registered as a practitioner in medicine, surgery, and midwifery, with also the privileges of the Apothecary's Licence.

Candidates must pass two Professional Examinations, called the Primary Examination and the Final Examination, which are conducted at separate times, partly in writing, and partly practically and orally. The Primary and Final Professional Examinations are held twice a year—viz., in June and November, or such other dates as may be determined.

Candidates who produce satisfactory evidence of having passed an examination for a Degree or Licence in Medicine, conducted by any University or Royal College in the British Empire, or by any Foreign University whose Degrees are recognised in the Foreign List of the Medical Register, will be exempted from the Primary Examination.

The subjects for Part I. of the Primary Examination are: Anatomy, Physiology and Histology, including Bio-Chemistry; and for Part II., Materia Medica and Pharmacy, Pathology, and Medical Jurisprudence and Hygiene.

For the Final Examination the subjects are: (*a*) Medicine and Clinical Medicine and Clinical Methods. (*b*) Surgery—Clinical, Ophthalmic and Operative; and Surgical Anatomy. (*c*) Midwifery and Gynæcology, and Practical Pharmacy and Materia Medica (if not taken at Intermediate Examination).

Each candidate before receiving his diploma must produce evidence that he has attained the age of 21 years. The details of the course of education required and syllabus of the examinations will be supplied by the Registrar at 95, Merrion-square, Dublin.

HOSPITALS AFFORDING PRACTICE RECOGNISED BY THE IRISH UNIVERSITIES AND CORPORATIONS.[1]

SIR PATRICK DUN'S HOSPITAL, Grand Canal-street, Dublin.—Classes both in Medicine and Surgery are held each morning from 9 o'clock from Oct. 1st till the end of June. Special classes for junior students will be held in the wards during the months of October, November, and December. A Resident Surgeon, with salary, is appointed annually. Ten Resident Pupils are appointed every four months. Twelve surgical Dressers and twelve Clinical Clerks are appointed each month. There are facilities for women students.

The practice of the hospital is open to all students, and the certificates are recognised by Dublin University, the National University and Royal Colleges of Surgeons of England, Ireland, and Scotland. It is an official "Treatment Centre" for venereal diseases.

Prizes and Medals.—Clinical medals and prizes amounting to about £21 each will be awarded in Medicine and in Surgery respectively in accordance with the will of the late Rev. Samuel Haughton, M.D., S.F.T.C.D. . Candidates who fail to obtain these medals and prizes will be awarded special certificates in Medicine and in Surgery provided they show sufficient merit.

Further information will be supplied by the Hon. Secretary to the Medical Board.

ADELAIDE HOSPITAL, Peter-street, Dublin.—Two resident surgeons are elected half-yearly and four or more resident pupils every six months. At the termination of the session prizes in Clinical Medicine, in Surgery, in Gynæcology, and in Dermatology will be awarded.

Prizes.—Wallace Beatty Memorial bursaries are awarded at the commencement of the winter session. In addition to the junior prizes the Hudson Scholarship, £30 and a gold medal, as well as a prize of £10 together with a silver medal, are awarded at the end of the session for proficiency in medicine, surgery, gynæcology, and pathology.

The certificates of attendance are recognised by all the Universities and licensing bodies in the United Kingdom. Further particulars may be obtained from the Secretary of the Hospital.

JERVIS-STREET HOSPITAL, Dublin.*—Founded 1718; rebuilt 1886. 130 beds. The operation theatre contains all modern requirements.

MATER MISERICORDIÆ HOSPITAL, Dublin. (Under the care of the Sisters of Mercy.)—This Hospital, containing 382 beds, is open at all hours for the reception of accidents and urgent cases. Clinical instruction is given by the Physicians and Surgeons at 9 A.M. daily. Ophthalmic Surgery is taught in the Special Wards and in the Dispensary. Surgical operations are performed daily. Connected with the hospital are extensive Dispensaries, which afford valuable opportunities for the study of general Medical and Surgical Diseases, and Accidents; a fully-equipped Biochemical Laboratory, a modern Electro-Massage Department, and Electro-cardiograph room. Instruction is given on Pathology and Bacteriology. Three House Physicians, eight House Surgeons, and 18 resident pupils are elected annually. Dressers and Clinical Clerks are appointed regularly and certificates given for merit. Leonard Prizes will be offered for competition annually. Certificates of attendance are recognised by all the Universities and licensing bodies in the United Kingdom. There is a Private Hospital for the reception of Medical and Surgical cases. A Training School and a Home for Trained Nurses are connected with the Hospital, and Nurses who have passed a qualifying examination can l obtained on application to the Lady Superior.

Entries can be made with any of the physicians surgeons, or with the Registrar, 13, Merrion-squa Detailed information may be obtained from t Secretary, Medical Board.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.- 150 beds are available for clinical teaching. A buildi containing 40 of these beds intended for the isolat treatment of fevers is attached to the hospital. T certificates of this hospital are recognised by all t universities and licensing bodies of the Unit Kingdom. Medical Clinical Clerks and Surgic Resident Pupils and Dressers are appointed eve three months. Two House Surgeons and a Reside Casualty Officer are elected twice annually. T Smyth Memorial Prize in Medicine, value £50, awarded in alternate years and is open to students the hospital who have attended for at least tv academic years. The next examination will be he in June, 1928. The Treasurer of the Medical Boa will give full information.

MERCER'S HOSPITAL.—This hospital contains 1 beds for medical and surgical cases, and arrangemen have been made with the medical officers of Cor street Fever Hospital whereby all students of t hospital are entitled to attend the clinical instructi of that institution and become eligible for the reside posts. There is a large dispensary for out-patie and a modern X ray department. An electro-cardi graph has been installed. Students of the hospi are permitted to attend the gynæcological departme where they receive practical instruction. There a special wards for the treatment and study of childre diseases. A gold medal is awarded annually to t best student. During the past few years the hospi has undergone extensive alterations in order to bri it up to modern requirements. A House Surgeon appointed annually. There are six men and two wom Resident Pupils, and Clinical Clerks and Dressers a appointed from members of the classes.

For further particulars apply to Dr. Leona Abrahamson, Hon. Sec., Medical Board, 40, Fi william-place.

RICHMOND, WHITWORTH, AND HARDWICKE HO PITALS (HOUSE OF INDUSTRY HOSPITALS), Dublin.* These hospitals contain 330 beds—130 for Surgi cases, 80 for Medical cases, 78 for Fever and oth Epidemic Diseases, and an Auxiliary Wing of 42 bed A Resident Physician and a Resident Surgeon a appointed each half year and are paid for th services. Resident Clinical Clerks are appointed ea quarter and provided with furnished apartmen and fuel. These appointments are open not only advanced students but also to those who are qualifi in Medicine and Surgery. The Dressers are select from among the best qualified of the pupils witho the payment of any additional fee. Women studen are eligible for election as residents, and spec apartments are reserved for their use. Extensi alterations and improvements have recently been ma in the X ray, electro-therapeutic, and electro-card graphic departments. For information apply Dr. G. E. Nesbitt, 71, St. Stephen's Green, Dublin.

ROYAL CITY OF DUBLIN HOSPITAL.—135 beds a a special wing for the treatment of fevers and co tagious diseases founded by the late Mr. Drummo There is a large nursery where special opportunit are afforded for the study of diseases of childre both medical and surgical. There are also spec wards for ophthalmic, aural, and gynæcological cas There is a largely attended out-patient departme where students are allowed to attend accidents a dress cases under supervision. Six resident pup are appointed every three months. A House Surge and a House Physician are appointed annually. F information apply to the Secretary.

[1] This list of the institutions recognised by the Conjoint Board of Ireland is supplemented in the regulations of the Colleges by those hospitals mentioned as recognised institutions in Scotland and England. The recognised facilities for clinical instruction in some of the Irish centres have been described.

* No returns.

* No returns.

DR. STEEVENS' HOSPITAL, Dublin (Kingsbridge).—50 beds, only 150 now in use. There is accommodation for 10 resident pupils, each of whom is provided with a separate bedroom, and board is supplied by the hospital at a reasonable rate. There is an Electric Massage Department and a "Sun-Ray" Department. Full information with regard to the terms for such residency can be had from the Resident Surgeon at the Hospital. Secretary: E. D. F. Banks.

ROTUNDA HOSPITAL, Dublin.—This institution is the largest combined gynæcological and maternity hospital in the British Empire. Over 4000 confinements are attended annually and upwards of 1000 gynæcological patients admitted. Students can take out their necessary gynæcological and midwifery practical courses. The work of the hospital is carried on continuously through the year, and consists of daily clinical instruction in the maternity department and examination and operations in the gynæcological department. Qualified students are given facilities for studying and assisting in the management of all abnormal cases so far as is practical. An antenatal dispensary is held three times weekly and all students are encouraged to attend. A special class in gynæcological examination and diagnosis is conducted by the Assistants to the Master. In addition there is a special class in operative obstetrics, limited in number. The pathological laboratory is under the supervision of a skilled pathologist. There is a fully equipped X ray installation under the care of a competent radiologist. The appointments on the staff of the hospital are given to qualified past students of the hospital who have taken the L.M. and consist of Extern Assistants for six months, one being appointed every three months. From these the Assistants to the Master are appointed. Women students can reside in the hospital on the same terms as men. The mess room and sleeping quarters have been decorated recently and reading rooms are provided. The L.M. is granted by examination after a six months' course. Fees for Intern students: one month £6 6*s*., months other than the first £4 4*s*., three months £12 12*s*., six months £21. Special gynæcological class £2 2*s*. per month. For further particulars apply to the Master, Dr. Bethel Solomons, F.R.C.P.I.

COOMBE LYING-IN HOSPITAL AND GUINNESS DISPENSARY FOR THE TREATMENT OF DISEASES PECULIAR TO WOMEN, Dublin.—This hospital contains 70 beds and consists of two divisions, one of which is devoted to lying-in cases and the other to the treatment of diseases peculiar to women. Lectures are delivered, practical instruction given, and gynæcological operations are performed in the theatres daily. There is a general dispensary held daily, at which instruction is given on the Diseases of Women and Children. There is a special afternoon dispensary held by the Master and his assistants, at which practical instruction in gynæcology is given. There is no extra charge for attendance at this Dispensary. A deep therapy X ray apparatus has been installed for the treatment of malignant cases. There is accommodation for intern pupils, who enjoy exceptional advantages of acquiring a thorough knowledge of this branch of their profession. Women students can reside in the hospital. Clinical assistants are appointed from amongst the pupils as vacancies occur. Certificates of attendance at this hospital are accepted by all licensing bodies. Students can enter for attendance at any time, but preference is given to those entering from the first day of the month. Further particulars may be had on application to the Master or the Registrar at the Hospital.

NATIONAL MATERNITY HOSPITAL, Holles-street, Dublin.—Established 1894. The hospital consists of Intern and Extern Maternity, Gynæcological Wards, and a Dispensary for the treatment of Diseases of Women and Children and an antenatal and post-natal branch. Every facility is given for the carrying out of practical work. Undergraduate and post-graduate courses are arranged at any time. Certificates of attendance at this hospital are recognised by all the licensing bodies. Clinical lectures are given daily and Oral lectures four times per week. The L.M. Diploma is given by special examination, which is held three times a year. Further particulars can be obtained from the Master or from the Secretary, Holles-street, Dublin.

ST. VINCENT'S HOSPITAL AND DISPENSARY, Dublin.—Established 1834. 200 beds. Clinical Lectures in Medicine and Surgery are held from October to June. Special classes for Juniors from October to December. Pathological and Bacteriological Demonstrations are given every Thursday, and instructions in the use of Laryngoscope and Otoscope for Senior students every Saturday. Medals and Prizes: the Bellingham gold medal in Medicine and the O'Farrell gold medal in Surgery are offered for competition at the end of the summer session, as well as junior prizes, also the Surgeon McArdle Prize, value £20. In the last term there was opened a new External Department and a new Pathological Laboratory. Dr. Meenan, Hon. Secretary, 28, Fitzwilliam-square.

WE take this opportunity of thanking the officials of Government Departments and the Deans and Secretaries of the various institutions for their kind coöperation in enabling us to bring the information contained in our Students' Number up to date.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCXXXVIII.

TREATMENT OF DISORDERS ASSOCIATED WITH EXAMINATIONS.

IT is the aim of every student faced with an examination to have all mental processes working at their maximum efficiency. There are several disorders of mind and body which may impair such efficiency and these can to a certain extent be prevented or avoided by judicious forethought. The processes concerned with the association of ideas are probably the most important in relation to examinations, and every candidate relies largely upon this form of mental activity to pull him through. Among a group of candidates there are always some whose difficulty is to get the association process set going, and others who are handicapped by a disability to sort out and set down in some form of order the multiple and complex ideas which flood their minds after reading their questions. Students seem to appeal for advice mostly to those among their seniors whose ordeals by examination are not too remote to be remembered in detail; but often a family practitioner could better help a student whom he has observed under various conditions of stress from childhood upwards. It is not usually difficult to separate those whose association-processes are inhibited by the very sight of an examination paper from those who are over-stimulated at the outset and need steadying. To either group drug therapy may be beneficial, but it must be carefully selected. For the first-named group a drug such as caffeine, which in small doses certainly stimulates the higher centres, is often beneficial taken half an hour or so before a written paper in the form of the effervescing preparation of caffeine citrate (gr. 60) or as a cup of good black coffee. For those whose higher centres tend to work at a feverish activity as soon as they begin to answer questions, alcohol taken immediately beforehand has been suggested. But those who make these suggestions require to have a singular familiarity with the subject's make-up, and those who act on them should know their own physiology with remarkable exactness.

The majority of candidates do not fall into either of these groups, and to them any form of drug-taking will only do harm. The practice of taking small doses of cocaine, prevalent in certain continental centres, is emphatically to be condemned.

Examination Phobia.

Most of the mental distress suffered by examination candidates comes into the category of phobia. The fears connected with written work are not so prevalent as those associated with viva voce examinations and can to a large extent be eliminated by working through questions without the help of books and keeping strictly to the time-limits usually allowed. This has the additional advantage that if sufficient old papers be worked through most of the questions met in the actual examination will have been answered before. For the fears associated with viva voce examinations preparation by a stern and preferably rude tutor with "ragging" propensities offers the best chance of a cure, but certainly such a tutor should be a private acquisition—as a class teacher he may benefit one student, but he will damage a dozen. In this connexion it should be remembered that the examiner with the rough manner does not necessarily mark lower than his gentler colleague, though there is little foundation for the common belief that the harsh in manner are the soft in action. Examiners make ample allowance for stage fright and usually give border-line candidates the benefit of the doubt. A trial trip, by which is meant taking the examination before the chances of passing are really hopeful, often gives valuable experience to the student, but the practice is to be condemned. It wastes time and vitiates the statistics by which the severity or laxity of the educational tests are estimated.

Revision of Work.

The peculiar muddled condition in which certain candidates find themselves at an examination is best dealt with by a thorough revision of the methods of preparation. For certain individuals cramming during the last week is almost always bad, while for others it is invaluable. This depends to a certain extent on what may be termed the reaction time of memory. Those who find that they can remember facts and figures best a few hours or days after committing them to memory do well to work almost up to the day of the test, glancing quickly through note-books or synopses covering the whole field of the subject of examination. Others, on the contrary, remember best a week or so after revising their work, and these persons will be well advised to slack off in the last week or to take a holiday. Even for the former class a whole day off immediately beforehand spent in quiet recreation will often be of great help, though it is difficult to convince them that this is so. Home worries should be reduced to a minimum before and during an examination. Over-anxious parents do not always realise what harm can be done by letting it be seen that they are worrying over the chances of success. The influence of love affairs appears to vary. Certainly any storms which seem to be inevitable had better either be postponed as far as possible or brought to a climax several weeks before the crucial days.

Diet.

Some candidates take little or no breakfast before an examination and have only starvation rations for lunch. While the eating of heavy meat meals is probably harmful, the free intake of carbohydrates is definitely beneficial and does much to prevent at least the form of headache due to acidosis. The midday meal between two three-hour papers should be the same as that taken on ordinary days with the addition of excess sugar in some form or other—e.g., chocolate. If alcohol is usually taken at lunch it should not be omitted.

Physical Disorders.

On the physical side many of the disorders occurring at examination times are physiological in origin, connected with over-stimulation of the adrenal-sympathetic mechanism. Tachycardia, diarrhœa and vomiting, fainting, frequency of micturition, drynes of the mouth, shaking of the limbs, and the "cold sweat" are the principal manifestations. Unless thes are very marked they can scarcely be regarded a pathological, and only in severe cases can any form o treatment be expected to give relief. Theoreticall drugs or endocrine preparations which stimulate th opposing autonomic nervous system might b expected to do good, but there is not yet sufficien known about such therapeutic measures. Tincture c belladonna (℥ 5) added to a mixture containing fu doses of bromide may do good in very severe case Troublesome vomiting is best relieved by a sedativ such as chloretone (gr. 5 to 10). For diarrhœa one of th opium astringent preparations such as pulv. kino. co (gr. 5 to 10) should be used, or codeine in pill form (gr. ¼ to ½) may be taken the day before the onset i nervous diarrhœa is expected. It will be seen tha the use of medicines like that of alcohol is dictate largely by the subject's own experiences—and eve these may be misleading.

Examination headache and examination sleeples ness are often difficult maladies to treat. For headach on the morning of an examination a combination suc as the well-known one of phenacetin, gr. 10, an caffeine citrate, gr. 5, will often give relief witho leaving any depressant after-effects. For sleeplessne a hot drink last thing at night with or without th addition of a little alcohol—very useful for th worrying type—and a dose of aspirin is often sufficien In severe cases of insomnia bromural, gr. 5, and adali gr. 5, are useful as hypnotics which do not usuall produce drowsiness on the following day.

Certain common affections may be present at th time of an examination and their routine treatmer may have to be modified to suit the situation. A attack of migraine may completely overcome candidate, who had better retire from the examinatio if such attacks are usually severe; the recurren of attacks may often be effectively stopped, at any ra for a time, by the well-known Gowers's mixture. I milder cases 20 gr. of phenacetin or aspirin or 15 g each of sodium bromide and sodium salicylate ma stave off an attack. In a bad attack of nas catarrh local treatment in the form of a medicate inhalation or menthol ointment will often giv temporary relief, while an irritating cough ca be suppressed by the use of a heroin linctus such a lozenge as one containing 3 gr. each extract of liquorice and ammonium chloride. A mi attack of influenza may be kept to a certa extent under control during an examination b repeated doses of a mixture containing quinin aspirin, and tinct. camph. co., but in severe cases th examination should be abandoned and no risk take The question of the infectivity of this and oth complaints should be borne in mind by the candida who proposes to sit at all costs.

ALAN MONCRIEFF, M.D., M.R.C.P. Lond.,
Medical Registrar, Middlesex Hospital.

GUILD OF ST. LUKE.

THE Guild of St. Luke was founded over 60 yea ago by a few medical students, chiefly to meet the own religious needs. It now makes a wider appe and its membership is open to all students a practitioners of medicine, both men and women, wh are members of the Church of England, the cler of which are eligible as Clerical Associates. Th Chapter meets in every month of each term, and festival service is held yearly at St. Luke's tid usually at St. Paul's or Westminster Abbey. Th year the service will be at the Abbey. Besides th parent Guild, there are a Women's Ward and Hospital Students' Branch in London. There a also a Midland Counties Ward and a Cambridge War Particulars of the objects and activities of the Gui and forms of application for membership can b obtained from the Secretary of the Guild of St. Luk Room B.B., King's College, Strand, W.C. 2.

THE LANCET.

LONDON: SATURDAY, AUGUST 27, 1927.

THE LIFE-LONG STUDENT.

A PERUSAL of the various Students' Numbers of THE LANCET, as they have appeared for more than three-quarters of a century, would afford an illuminating panorama of medical education in its developments throughout the period; and in return for even cursory glances at haphazard specimens of these Numbers there will be obtained pictures illustrative of the principal moves in the construction of the present scheme of training for medical students. In the early Numbers great play was made with the personalities of the staffs—these were the times when apprenticeship to the staffs was the doorway to success. Then the question of the fees paid by the students began to be of great importance, for the value of obtaining medical qualifications was becoming clear to all, and this could only be managed by definite payments for definite instruction by a class whose members were often poor. With the passing of the first Medical Act, the medical curriculum, though only of three years' duration, became standardised, and the advantage of entering the profession through the portal of a particular school became less, as the significance of the right use of a definite period of training became apparent. When this position was reached there was less reason to balance the claims of various schools in various parts of the country on general grounds.

But as, with the progress of medical science, came the lengthening of the curriculum and the multiplication of compulsory subjects, these things were reflected in the Students' Numbers by a recapitulation of the claims of different medical schools to provide the variously elaborated courses of study. When we first attempted to summarise in an educational guide the story of medical education, it was done with the view of placing before the students the main advantages that were offered by particular schools, the practice of those schools and the personalities of the staffs; and the amount of the fees could be used often as a deciding factor in any advice that was offered. Scholarships, bursaries, and prizes were fewer in number, and, being mostly small, the school which had the larger rewards for industry and brains stood out favourably in comparison with other schools. This obtains to-day with less force because of the growing frequency with which the student of the prize-getting class is already endowed before he reaches the medical school proper. The connexion of the medical schools with the universities is a thing of comparatively modern growth, but has led in its train to opportunities for the well-equipped and industrious that were formerly absent. The last phases of change in the medical curriculum have been brought about by many-sided developments in the great medical services, fighting and civilian, state, municipal, and institutional, with their corollaries in the provision of special diplomas and the growth of post-graduate schemes. And thus our annual educational supplement to-day omits many things that have been its salient features in the past in order to render the present with due proportion. Prominence must now be given to post-graduate schemes and to the examinations which guard the special diplomas. The practitioner not only feels the need of maintaining and developing his knowledge, but often desires to specialise in accordance with his bent; for the official medical man a period of intensive study is enjoined. The statement, so frequent in inaugural addresses, that a medical man is always a medical student, no longer depends for its force upon ideal considerations, but is accepted as a fact to be dealt with along practical lines.

But for the simple counsels which we were wont to attempt, directing them to those in pupillary state, there is undoubtedly room, and we welcome a memorandum from the Registrar of the General Medical Council, published last month, which deals with the procedure to be adopted by those who desire to enter the profession of medicine. The notes on the training and on the prospects of the future careers that will be open to the qualified man, written in untechnical language, describe briefly the course of the student as it can be followed through our pages this week. A table is included setting out the expenses of the educational career, and the costs of tuition and examination with an estimate of the sum required for maintenance for the duration of the curriculum. The table is a model of compression, and, indeed, is in places too brief, for the details in respect of some of the licensing bodies and medical schools are absent, though in respect of others they are full and accurate. The memorandum, which makes no claim to be exhaustive, will serve the useful purpose of focusing the minds of parents and guardians on the outstanding facts attending entrance upon the medical career. We believe that "The Conduct of Medical Practice" will be a useful guide throughout the medical life, supplementing the words of the General Medical Council throughout. The memorandum closes with an endorsement of the view that there is no evidence of an excessive supply of medical practitioners of the kind that should deter those who feel drawn towards the medical life from following their desire. The way is hard and long, but with enthusiasm in surmounting early difficulties there will come a joy in facing the greater problems.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—A fortnight's course at the Queen's Hospital for Children will begin on Sept. 12th; the fee will be £3 3*s*. On the same date a three weeks' course will begin at the Royal Westminster Ophthalmic Hospital, including special demonstrations and clinical instruction and operations every afternoon (fee £4 4*s*.). For a fortnight from Sept. 19th the Royal National Orthopædic Hospital will hold an all-day course, with lecture-demonstrations in the mornings and operations and out-patient work in the afternoons (fee £2 2*s*.). During the same period there will be an all-day course in medicine, surgery, and the specialties at the Westminster Hospital (fee £3 3*s*. or £2 2*s*. for either week). During October courses will be given on the following subjects: Ante-natal care at the Royal Free Hospital; cardiology at the National Hospital for Diseases of the Heart; diseases of children at the Victoria Hospital and Paddington Green Hospital; diseases of the throat, nose, and ear at the Central London Throat, Nose, and Ear Hospital; electro-therapy at the Royal Free Hospital; gynæcology at the Chelsea Hospital; ophthalmology at the Royal Eye Hospital; tropical medicine at the London School of Hygiene and Tropical Medicine; and neurology at the National Hospital, Queen-square. The first of a series of lectures entitled Practical Hints on Medicine, Surgery, and the Allied Specialties will be delivered on Oct. 17th by Sir Humphry Rolleston, and the series will be continued by other lecturers on Mondays until Christmas. Weekly clinical demonstrations in medicine, surgery, and ophthalmology are to be given at appropriate hospitals. These demonstrations and lectures will be open to all members of the medical profession without fee, and further details will be published later. Copies of the syllabuses for all courses, lectures and demonstrations may be obtained from the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1, and will be supplied on publication to those who wish to receive them regularly. The *Post-Graduate Medical Journal* is also obtainable from the Secretary (6*s*. per annum, post free).

Special Articles.

THE ART OF LEARNING ANATOMY.

BY ROBERT D. LOCKHART,
CH.M. ABERD.,
LECTURER ON ANATOMY, UNIVERSITY OF ABERDEEN.

WHILE the world, of necessity, has an eye and an ear for the clock, remarkably few students form and adhere to a time-table for their private work. Each subject should be assessed according to the hours devoted to it in the university curriculum, and private study should be allotted in exact proportion. Many a student rides a hobby upon anatomy to the detriment of physiology, but the athlete times his varied exercises to balance his muscular development, and the best students have a time system.

Anatomy affords ample scope for illustration of the right and the wrong way to set about a course of study, and I propose to consider the manner in which this subject may best be approached.

Dissection.

It is a falsehood to assert there is no royal road in anatomy. Dissection is the royal road and follows a pass through difficult mountains to pleasure and peace of mind. Many students do not follow this pass and waste their energies upon the stony mountain-side. These will never experience the freedom of confidence, and will always be gripped in the toils of the text-book and fogged by dreary descriptions. They will always be a prey to the panic of the eleventh-hour oblivion of memory, when Timothy's nervous housemaids and Treves's abilities in peritonitis will be an inadequate refuge.

Dissection is a handicraft demanding the skilful handling of suitable instruments; there is delight in the use of a sharp scalpel, but the blade may be blunt within an hour, thus wasting work and time. In dissection as in other trades good tools are half the job. Forceps are used continually, and must be well-balanced, responding to slight pressure; fingers ache in a few moments if they have to play the part of a vice and no pleasure can be got from an instrument whose points persist in twisting at the critical moment.

No one can get to grips with his work when one eye is on a new suit and the other on a greasy table; this is the beginning which leads to the survey of somebody else's dissection from a discreet distance. Clothing should be as business-like as possible. The dissecting table, morover, should be kept tidy; a confusion of soaking text-books, scalpels, saws, loose bandages, and wood blocks is not conducive to good work nor even to good thinking.

The hands, again, must be trained. It is not uncommon to find that a student whose manual inefficiency beggars description has feet attuned to the intricacies of time and to a Charleston jugglery that puts his hands to shame. The hands must be kept dissecting; soon they will be learning to palpate and percuss and their owner will to a certain extent depend upon sensations of touch in the diagnosis of diseased from normal states.

Anatomical science has constantly flourished with research upon the living and dwindled with research upon the dead. Therefore the student should study the dead upon the living. The detailed and prolonged examination of his own body ought not to be a haphazard event, but a systematic habit. He should endeavour to locate structures that his book does not describe under surface anatomy; he should draw the surface markings on his own limbs and study the variation caused by movement. Even men in their final year have missed the coracoid process; yet everyone has two, and they can even be seen in a thin person.

Books.

The text-book of practical anatomy, and indeed all anatomical text-books, ought to be read in front of the specimen; each line of the book must be verified by dissection or observation, so that the disposition of the parts becomes so evident that the mind is not taxed to remember. The five years of medical training are worse than wasted, unless they breed a determined conviction to treat all text-books and opinions, no matter whose they are, with no more than mere tolerance until the facts can be observed and the statements verified. There is, therefore, danger in too many books. One book on practical anatomy is necessary to guide dissection and secure the demonstration of the various structures entering into the formation of any one region. But these same structures may traverse several regions and may have intricate origins and terminations on either side of the particular point of dissection; so it is necessary to consult a systematic book dealing in consecutive detail with the disposition of the complete structures. The two books are consulted *pari passu*, the practical becoming a kind of index suggesting the subjects whose continued description will be found in the systematic work. This admits of the use of a brief practical book with a reliable systematic one. Where on the other hand the practical book gives detailed descriptions there is not the same need for close study of a systematic text which may then be used merely to coördinate the practical study. A book without pictures is useless in the absence of dissections.

A sickening feeling is produced by learning a page of Gray's "Anatomy" by heart; the student looks to see how many hundred pages the book contains and wonders whether some serious error of judgment has not been committed in presenting such a solid conglomeration for his assimilation. No wonder he takes the wrong turning and buys a pocket edition. The point that needs emphasis is that whatever book he uses he should regard it as a liability necessitating liquidation. Each word he takes from it must be verified upon the specimen until the knowledge is his very own.

Technical terms are often a source of confusion, and knowledge of Latin and Greek at school does not always mean intelligent appreciation of the names derived from them. The dissecting-room is so foreign to the school-room that it may never occur to the student that the latissimus dorsi muscle is so called because it is the broadest muscle of the back. Who stops to argue why the name of tailor should be applied for the sartorius—instead of the name of tinker, soldier, or sailor? Who remembers that the word tragus, which means a goat, is applied to a part of the ear which often has a little tuft like a goat's beard, beside it? The unbiased beginner may find that at least the principles of the new nomenclature are more intelligible than those of the old.

Reconstruction.

Bones often breed dislike, but they carry the burden of the subject; the whole story literally hangs upon them and they will teach two-thirds of anatomy. The bones of the part being dissected should be at hand; they should be carefully drawn and clothed in their related structures. This drawing is a talent secured by honest trial and is a language in itself. It reveals the accuracy and defects of knowledge in a few moments, while they might be hidden in pages of words. It is useful to test the memory by constructing diagrams, and in the examination-room a good sketch is of the utmost value. Reconstruction of a dissection in plasticine or wax is an even better way of impressing on the mind the disposition of the various structures. This is a method which lends itself admirably to fashioning the soft parts upon the dry skeleton, and though it

akes a good deal of time, it leads to thorough knowledge and self-confidence.

Speed.

Results ought to be commensurate with the time spent in dissection. As soon as the relevant description has been read the student should seize his scalpel and forceps with determination to demonstrate the structure as quickly as possible. Michael Angelo is said to have approached his blocks of marble with definite fury. There is no need to remove the last vestige of fat and fascia when the general disposition is plain and an effort should be made to secure speed. Many students waste nearly all the time they spend in the dissecting-room; there is no activity beneath their cloak of attendance, and their scalpels drum a disintegrating tattoo to the hum of idle words and the destruction of the part.

Lectures and Examinations.

To get the best out of a systematic lecture the student should prepare the subject beforehand—not from a senior's notes but by summarising the text-book—and should then check and supplement his attempt according to the points emphasised in class. This is the way to meet the teacher on an equal footing, with pleasurable anticipation, knowledge, and critical reception, free from the strain of cramped knuckles and missing words.

Examinations are in many ways trying but there is a real endeavour to throw the test upon the teaching curriculum. A preliminary study of previous questions is an admirable training for written papers. The candidate who finds himself stumped by a question should forget his memory and try to reason. Oral examinations are most important. The candidate who knows the answer should be rapid in replying and should say what he knows in an interesting tone with decided conviction. He will lose little for an error made in such a manner, whereas he will get no credit for the low faltering hesitating whisper, even though it is correct. The examiner is testing knowledge of the body. If he asks a muscle's nerve-supply he should be made to see the nerve actually entering the muscle; the name is much less important. If the student does not know the muscles which a nerve supplies, he should take up the nerve and follow each branch to its end and the specimen will speak for itself. The examiner will soon determine that such a candidate is essentially practical and reliant upon his own hands and eyes, and will pass him without a doubt. It is useless to let the face wrinkle with that tip-of-the-tongue-but-won't-come-off expression—the eyes wandering round the room before seeking the ceiling in a final appeal for the nerves to the digastric muscle. The examiner knows the symptoms of text-book memorising with no dissection, and he knows that a student who has learnt in this way is not a safe proposition.

Enthusiasm.

In learning anatomy, as in other pursuits, one of the greatest assets is enthusiasm. This enthusiasm is often damped by a lack of understanding of the importance of the subject. The student should always bear in mind, therefore, that once he has mastered the elementary facts of anatomy and physiology and become conversant with clinical methods he is in ripe condition to argue the steps of diagnosis, and his opinions will have become worth while, for the best opinions are made upon this very foundation. Horsley was teaching and performing delicate experimental operations upon animals long before he was qualified, and Pasteur, a chemist, took probably the foremost place in the making of medical history because of his passion to prove for himself. The medical curriculum becomes extensive for a bird's-eye view, but whoever knows his anatomy on the living body and adheres to principles of physiology, has his equipment in good order. Those who regard anatomy as a yoke, liberation from which is secured for ever by passing the professional examination, are making a dreadful mistake.

NAVAL MEDICAL SERVICE.

IN the Navy the young medical officer sees the world in congenial company and with an assured position, the pay is good, the pensions are commensurate, and the opportunities offered now for scientific work are real, while, if they are taken, promotion awaits the officer on grounds of professional merit.

As a result of the recommendations of the Inter-Departmental Committee on the Medical Branches of the Fighting Services, the following changes in the conditions of service have been approved.

(1) *Increase in the Establishment of Surgeon Captains.*—The maximum number of Surgeon Captains authorised to be borne have been increased from 16 to 20. Two Surgeon Captains have been appointed to the R.N. Hospital, Haslar, as Professors of Medicine and Surgery, respectively, on instructional duties connected with the general courses described below. The appointment of Director of Medical Studies, Naval Medical School, R.N. College, Greenwich, will in future be held by a Surgeon Captain, and a Surgeon Captain has been appointed to the R.N. Hospital, Malta, as second in charge.

(2) *Increase in Specialists' Allowances and Number of Appointments.*—The number of Specialist appointments has been increased from 46 to 60, and the new appointments include Specialist posts in Medicine, Surgery, Radiology, and Hygiene. The allowance payable to holders of Specialist appointments has been increased from 2*s.* 6*d.* to 5*s.* per day.

(3) *Grant of Charge Pay.*—The grant of charge pay will be made as from July 1st, 1926, on the following scale for Medical Officers in charge of hospitals and sick quarters: Surgeon Rear-Admirals and Surgeon Captains, 10*s.* a day; Surgeon Commanders, 5*s.* a day.

(4) *Professional Courses.*—(*a*) *General Courses:* Every Officer below the rank of Surgeon Captain, except when he has just vacated an appointment at a Home Hospital or is due to take his promotion course, will be appointed, if his services can be spared, once in every four years to the R.N. Hospital, Haslar, for a course of instruction of not less than four months' duration in Clinical Medicine and Surgery and allied subjects. At the end of the course, instead of being placed on Unemployed Time, the Officer will be appointed for duty at one of the R.N. Hospitals at Haslar, Chatham, or Plymouth, unless or until he receives an appointment elsewhere. (*b*) *Specialist Courses:* Every Officer selected to hold a Specialist appointment will, provided his services can be spared, undergo a course of not less than six months' duration in his special subject at a civil hospital in London or other teaching centre, and will subsequently undergo a course of three months' duration in that subject every four years while he is employed as a Specialist. (*c*) *Senior Medical Officers' Courses:* The existing Senior Medical Officers' Courses will to a large extent be superseded by the General and Specialist Courses described above, and their number will therefore be capable of reduction without detriment to the professional opportunities in the Service, but the reduction will not be made until the new courses have been in operation for some years. The institution of General and Specialist Courses will necessitate an increase in establishment, and they cannot therefore be put into full operation until this increase has taken place, but the new arrangements will be inaugurated as soon as possible.

(5) *Time in Hospital Appointments.*—An Officer who enters the Service on or after July 1st, 1926, and who has held, for a period of not less than one year before the date of his entry into the Service, a resident appointment as Medical or Surgical Officer in a civil hospital after becoming a qualified medical practitioner, to be eligible, at the discretion of

the Admiralty, to have his seniority antedated by not more than one year, provided that the appointment is one recognised by the Admiralty for this purpose, but this concession will not ordinarily be granted where the interval between the termination of the hospital appointment and the date of entry into the Service exceeds six months. The period of not less than one year in a "resident" appointment may, at the discretion of the Admiralty, include a period of not more than six months spent in a "non-resident" appointment recognised by the Admiralty.

The increase of seniority allowed under the above conditions shall not render an Officer eligible to receive pay before the date of his actual entry into the Naval Service, but the time concerned shall reckon for increase of full, unemployed, and half pay while on the active list, and retired pay or gratuity on retirement or withdrawal, provided, in the case of a gratuity, that the Officer has completed three years' full pay service in the Royal Navy, that is, exclusive of the time spent as Resident Medical or Surgical Officer in a civil hospital.

In the event of a temporary Officer, or an Officer entered for short service (*v. infra*) being transferred to the permanent list on or after July 1st, 1926, he may be granted the above concession, at Admiralty discretion, under similar conditions to those applicable to candidates who may enter the permanent service direct, except that the time shall not count for gratuity on retirement or withdrawal.

A candidate who is over the normal age limits for entry may be entered, notwithstanding, provided that the period of antedate for which he is eligible brings him, if deducted, within the ordinary limits.

Rank of Surgeon Lieutenant-Commander will be granted to surgeons at the expiration of six years from date of entry, and the point upon which stress should be laid is that special promotion can be made in cases of conspicuous professional merit, which is thus placed on a par with general service. Six years later the period of promotion to Surgeon Commander is reached, after the qualifying examination has been passed, when again special promotions can be made for conspicuous professional merit as well as for distinguished service; but promotions are limited in number, save, of course, for gallantry in action. This recognition of professional attainment should prove a very real incentive to progressive scientific work. The same principle prevails in the higher ranks. Promotions to Surgeon Captain and later to Surgeon Rear-Admiral are made strictly by selection, but are confined to officers who prove fitted, both professionally and as administrators, for this rank.

Naval life may lead to opportunities for putting into practice much of what has been learned in the clinical wards of a hospital. Further, the opening for preventive medicine is large and many-sided, while appointments to the large shore establishments enable medical officers to keep their work modern. New chemical explosives, as well as the extraordinary behaviour of common articles under extraordinary conditions of stowage, furnish perpetual problems and surprises for the medical officer. The health lectures which he is bound to deliver will often afford a starting point of work that may develop into great professional interest. Numerous changes have been introduced during the last 20 years into the naval dietary, many of which were the outcome of representations and research by naval medical officers. The work wants carrying on, for much of it has gone to show that the food problem is very complicated. Every medical officer on board ship should make himself acquainted with food values and the human powers of assimilation under varying conditions of work and climate, and here there is ample scope for research. The modern requirements of gunnery and navigation necessitate precision in their use and have made ophthalmology a valuable subject for study in the Navy. The physical training of both officers and men is based on physiological axioms which are peculiarly the field of the medical officer. Lastly, there is the whole field of venereal and tropical disease.

The young medical officer need not be afraid that his work will be without scientific interest if he takes the opportunities offered him.

Conditions of Service.

The rates of pay of the Medical Service are subject to periodical revision in the light of the cost of living, and it is necessary to indicate as closely as practicable the extent and methods of the periodical revision.

In order that students may be under no misapprehension regarding their remuneration should they decide to join the Naval Medical Service, it should be clearly understood that when the pay of naval officers was revised in 1919 it was definitely laid down that 20 per cent. of the rates of full pay, unemployed pay, half pay, and retired pay was to be considered as due to the high cost of living in 1919, and that it should be subject to change periodically either upwards or downwards according as the cost of living rose or fell. The first revision took place in July, 1924, when all the rates were reduced by approximately 5½ per cent.; the second revision took place in July, 1927, when all rates were reduced by ½ per cent.; and further revisions (not necessarily reductions) are due every three years—i.e., in July, 1930, and so on.

The pay of the Naval Medical Service is shown in two tables, one showing the scale introduced in 1919 which is described as the standard rates and of which 20 per cent. is variable, and the other showing the actual scale in force from July 1st, 1924, to June 30th, 1927.

For the time being the regulations for entry by examination into the permanent service are in abeyance, but a short-service scheme providing for transfer to the permanent service has been inaugurated. The regulations for the entry of surgeon lieutenants under this scheme provide for the usual qualifications of registration, good character, physical fitness, and age—the age not to exceed 30 years. The conditions of service are a three years' engagement with an option of a further year, to serve when and where required under the general rules of the service as regards discipline, and to rank with, but after, surgeon lieutenants in the permanent service, and to receive two calendar months' notice of services being no longer required.

As from July 1st, 1927, the pay is £1 4*s*. 10*d*. (standard rate £1 6*s*. 6*d*.) per day or £453 4*s*. 2*d*. (standard rate £483 12*s*. 6*d*.) per annum, while there is a gratuity not subject to variation with the cost of living, on discharge of £8 6*s*. 8*d*. for each completed month of service. All officers during service are accommodated and victualled on the usual service scale or receive lodging money and provision allowance in lieu, at rates subject to periodical revision. The present rates of lodging money and provision allowance are £80 and £55 a year respectively. Unlike permanent officers, medical officers entered for short service are not liable to periods of unemployment on unemployed or half pay or eligible for retired pay in respect of service. If, however, such an officer were invalided for a cause certified by the competent naval medical authority as attributable to the conditions of service, he would be eligible for disability retired pay in lieu of the gratuity on discharge referred to above. Similarly, in the event of his death from a cause attributable to the service his widow and children would be treated in the same manner as the widow and children of an officer on the permanent list. There is an equipment allowance for ordinary uniform of £50, but the officer provides himself with a pocket case of instruments and a stethoscope.

A short-service surgeon lieutenant after six months' service, on application to the Secretary of the Admiralty, may be considered for transfer to the permanent service on a satisfactory report being received

om the senior medical officer of the Squadron, ospital, or Depôt in which he has served or is serving to his professional ability, and a favourable report m his commanding officer as to conduct. Such ndidates must have been under the age of 28 on ning for short service, and officers so transferred ll not be eligible for the gratuities provided. They ll be permitted to count their seniority from date entry for short service for purposes of promotion d for increment of full pay, and similarly they will permitted to count their service from the date of ry for purposes of retired pay, but for purposes retiring gratuity on the permanent officers' scale ir services will be reckoned only from the date of nsfer to the permanent list, this date being that receipt in the ship or establishment in which the cer is serving of the order for his transfer to the manent list. Until that date he will retain his porary rate of pay.

f a short-service lieutenant transfers to the permanent service he will then come under the following nditions of pay and pensions :—

Standard and Present Rates of Pay.

Rank.	Standard rate.				Rate from July 1st, 1927.			
	Year of 365 days.		One day.		Year of 365 days.		One day.	
	£	s. d.	£	s. d.	£	s. d.	£	s. d.

„ 6 „	967	5 0	2	13 0	—		2	9 10
„ 9 „	1040	5 0	2	17 0	—		2	13 6
g. Capt. on promotion	1186	5 0	3	5 0	—		3	1 2
After 3 years	1277	10 0	3	10 0	—		3	5 10
„ 6 „	1368	15 0	3	15 0	—		3	10 6
„ 9 „	1460	0 0	4	0 0	—		3	15 2
g. Rear-Admiral ..	1916	5 0	5	5 0	—		4	18 8
lical Director-General	2500	0 0	—		2350	0 0	—	

On first appointment to the Service, medical officers l receive full pay from date of appointment, but ject to the provisions of Article 1347 of the King's gulations.

Officers of the permanent service are eligible during iods of unemployment for unemployed pay and f pay. The rates of unemployed pay and half pay, l the conditions under which they are granted, are same as in the dental branch and are set forth in ail later in this article.

Flag Allowances.

An allowance of 5*s.* a day in addition to full pay granted to the Senior Medical Officer of a flag-o bearing the flag of a Commander-in-Chief. allowance of 2*s.* 6*d.* a day is granted to the ior Medical Officer of a ship bearing other flags broad pennants.

Standard Rates of Retired Pay.

ompulsory retirement will be as follows :—

i) Surgeon Rear-Admirals retire at the age of 60 with ed pay at the rate of £900 per annum plus £22 per um for each year's service over 27 years counting for ed pay, subject to a maximum rate of £1010 per annum. however, less than 27 years' service counting towards ed pay is rendered, a deduction of £22 per annum is e for each full year wanting to complete that period, ect to a minimum of £790 per annum.

ii) Surgeon Captains retire at the age of 55. Maximum ed pay, £900.

iii) Surgeon Commanders retire at the age of 50. Maxi-n retired pay, £600.

iv) Surgeon Lieutenant-Commanders and Lieutenants e at the age of 45. Maximum retired pay, £450.

Subject to these maxima, the rates of retired pay for Surgeon Captains, Surgeon Commanders, Surgeon Lieutenant-Commanders, and Surgeon Lieutenants are as follows :—

Age on retirement.	Retired pay.	Period of service (years) counting towards retired pay.	(A)		Age on retirement.	Retired pay.	Period of service (years) counting towards retired pay.	(A)	
			Addition.	Deduction.				Addition.	Deduction.
	£ (p.a.)		£ (p.a.)	£ (p.a.)		£ (p.a.)		£ (p.a.)	£ (p.a.)
55	790	24	22	15	47	562	20	15	15
54	765	24	22	15	46	525	20	15	15
53	742	23	22	15	45	487	19	15	15
52	720	23	22	15	44	450	19	15	15
51	697	22	22	15	43	412	18	15	15
50	675	22	15	15	42	375	18	15	15
49	637	21	15	15	41	337	17	15	15
48	600	21	15	15	40	300	17	15	15

(p.a.) = per annum.

(A) Addition for each full year's service in excess of that specified in column 3 or deduction for each full year wanting to complete that period of service—addition or deduction limited to five years in each case.

Twenty per cent. of all the rates of retired pay referred to above is variable with the cost of living, and the rates at present in course of payment are approximately 6 per cent. below those given above.

Medical Officers are eligible to withdraw with certain gratuities on the same scale as for Dental Officers (v. infra).

DENTAL BRANCH.

1. The Naval Dental Service offers similar opportunities to qualified dental surgeons except that higher rank than that of the recently instituted Surgeon Captain (D) is not open to them. They are provided with suitable surgery accommodation equipped with modern appliances and supplied with all material required for their work, and there is every opportunity for them to maintain a high standard of professional skill.

2. Candidates are required to produce certificates of birth, registration, and of character, and must be physically fit for active service anywhere. An outfit allowance of £50 is payable to officers finally entered and commissioned. The rank of Surgeon Lieutenant-Commander (D) is attained on the completion of six years' satisfactory service. Promotions to Surgeon Commander (D) and Surgeon Captain (D) are made strictly by selection from the rank next below and are confined to officers who prove fitted in every respect for these ranks. The present establishment of dental officers is : 1 Surgeon Captain (D), 3 Surgeon Commanders (D), 60 Surgeon Lieutenant-Commanders (D) and Surgeon Lieutenants (D).

3. Provision has been made for candidates who, at the time of passing the examination, hold or are about to hold an appointment as Dental Officer in a recognised Civil Hospital. The time concerned, provided it does not exceed six months, may reckon for increase of full pay while on the active list. Surgeon Lieutenant-Commanders (D) of over two years' seniority will be eligible for a three months' Post-graduate Course while borne on full pay.

4. As in the case of the medical branch, 20 per cent. of the rates of full pay, unemployed pay, half pay, and retired pay introduced in 1919 is considered as due to the high cost of living in 1919 and subject to change periodically either upwards or downwards according as the cost of living rises or falls. The first revision took place in July, 1924, when all the rates were reduced by approximately 5½ per cent., the second revision took place in July, 1927, when all rates were reduced by ½ per cent., and further revisions are due every three years—i.e., in July, 1930, and so on. The following table and paragraphs show the standard rates introduced in 1919, of which

20 per cent. is variable, and the present rates which will operate from July 1st, 1927, to June 30th, 1930.

Full Pay.

Rank.	Standard rate.				Rate from July 1st, 1927.

After 3 years	—		3	7 6	—		3	3 6
„ 6 „	—		3	12 6	—		3	8 2
„ 9 „	—		3	17 6	—		3	12 10

On first appointment to the Service, Dental Officers will receive full pay from the date of appointment, but subject to the provisions of Article 1347 of the King's Regulations, 1913.

Dental Officers are eligible for the same rates of lodging and provision allowances as other officers of equivalent rank and are entitled to the same privileges. The rates of half-pay are :—

Unemployed Pay and Half Pay.—A distinction is to be drawn between—

(*a*) Officers awaiting employment.

(*b*) Those who are permitted for private reasons which the Admiralty regard as satisfactory to refuse an appointment or to have their appointment cancelled or who are unemployed at their own request or in consequence of misconduct.

In the former case—

(*a*) Officers are to receive unemployed pay as follows :—

For the first six calendar months full pay of rank (without allowances).

For the next six calendar months :—

Rank.	Standard rate per diem.			Rate per diem from July 1st, 1927.		
	£	s.	d.	£	s.	d.
Surgeon Lieutenants (D)	0	17	0	0	16	0
Surgeon Lieutenant-Commanders (D) ..	1	2	6	1	1	2
Surgeon Commanders (D)	1	7	6	1	5	10
Thereafter :—Half the full pay of their rank and seniority on the Executive Officers' scale, namely :—						
Surgeon Lieutenant (D)	0	8	6	0	8	0
„ „ of 4 years' seniority	0	10	0	0	9	5
Surgeon Lieutenant-Commander (D).. ..	0	15	0	0	14	1
„ „ of 3 years' seniority	0	16	0	0	15	0
„ „ of 6 years' seniority	0	17	0	0	16	0
Surgeon Commander (D)	1	0	0	0	18	10
„ „ of 3 years' seniority	1	2	0	1	0	8
„ „ 6 „ „	1	4	0	1	2	7
„ „ 9 „ „	1	6	0	1	4	5
Surgeon Captain (D)	1	12	6	1	10	7
„ „ over 6 years ..	1	17	6	1	15	3

Unemployed pay will not, however, be granted in cases where an officer is undertaking continuous professional work for which payment is made.

In the latter case, (*b*), Officers may receive half the full pay of their rank and seniority on the Executive Officers' scale.

Periods during which unemployed Full Pay or Unemployed Pay are received will only count as half-pay time—that is, as one-third of full service.

An Officer who is permitted, for private reasons, to decline an appointment, or to have his appointment cancelled will not be entitled to any Unemployed Pay. In such cases, Officers may be placed on Half-Pay.

The conditions of retirement, Widows' Pensions, Leave, &c., are the same as for Medical Officers of equivalent rank and seniority.

Arrangements are also made whereby officers may be allowed to withdraw from the Service after four years' service and receive gratuities on the followin scale :—

Gratuities will be awarded on retirement and withdraw on the undermentioned scale.

Rank.	Gratuity.

ARMY MEDICAL SERVICE.

ROYAL ARMY MEDICAL CORPS.

THE publication of the Royal Warrant of 1926 ha removed many of the grievances of officers of th Corps, and this Service can again be recommende as a career to young medical men. Competitiv examinations for regular commission, which hav been in abeyance for some time, will again be hel half-yearly in January and July. These examinatior in medicine and surgery are entirely of a clinical an practical character, partly written and partly oral.

The regulations for admission giving full detai should be obtained from the Permanent Unde Secretary of State (A.M.D. 1), War Office, Whitehal London, S.W. 1, and carefully studied. A person interview with a representative of the Director-Genera Army Medical Services, is readily obtainable.

The rates of pay and allowances are good; th opportunities of post-graduate study are generou and the work is varied, responsible, and interestin The gratuities after certain periods of service enab an officer should he so desire to leave the Service wit a capital sum large enough to go a long way towar re-establishing himself in civil life, and, further, th knowledge of the world and the comradeship of h fellow officers that he has gained in the Army will l of no small value to him.

New entrants are commissioned in the rank Lieutenant, and the first six months of service a spent on probation, during which time they underg in addition to their Military training at the Roy Army Medical Corps Depôt at Aldershot, a pr batory course at the Royal Army Medical Colle in London in Hygiene, Pathology, Tropical Medicin Military Surgery, Recruiting, the prevention an treatment of Venereal Disease, and the elements Army Administration. At the end of this cours and after qualifying at the necessary examination their commissions are confirmed, and they take the places in seniority according to the total mar obtained at all examinations up to that date. Office Training Corps service with possession of Certificat "A" or "B" (Medical) carry a definite value marks in this total.

An entrant who is holding or about to hold at th time of the entrance examination a resident Hou Appointment at an approved Civil Hospital may l seconded while holding such an appointment up to maximum period of 12 months. A candidate wh has held such an appointment within six months entry may be granted an antedate up to 12 month in respect of the period the appointment was hel This secondment and antedate counts in all respec as commissioned service, except that pay will not b issued for that period.

After a total period of one year's service at hon the young officer goes abroad, probably to India, f his first tour of foreign service. Here he gains h first practical experience of tropical disease an tropical hygiene, and possibly his first experience active service on the frontiers of India. His to abroad lasts five years, with probably six month leave home during that time. On returning home th

A.M.C. officer has the opportunity to decide whether will remain in the Corps or accept the gratuity of 000 after seven years' service, and try his fortune civil life. If he elects to remain, he will, between s eighth and twelfth year of service, undergo a course post-graduate study at the Royal Army Medical llege and the London Hospitals of five months' ration, followed by a course of study of a special bject selected by himself, provided he has shown ecial aptitude in the post-graduate course or during s previous service. During this period of study he mains on full pay, and the fees for the courses are d by the State. When qualified in his special bject, the officer becomes entitled to specialist pay 5*s.* per day when holding a specialist appointment. er this post-graduate course the officer probably ceeds abroad again and promotion to Major idly ensues, and from that time onward the officer eives regular successive increases of pay, and is gible for additional and charge pay as well. The ectorates of Hygiene and Pathology and the pointment of two serving officers as Consultants Medicine and Surgery have been instituted and ve proved a marked success, all these appoint- nts being of the rank of Colonel or Major- neral.

Under these conditions the possibilities for good rkers are very great in the Royal Army Medical ps. There is scope for original research in tropical ease, in preventive medicine, and in bacteriology, well as in the large clinical field open to the specialist Medicine, Surgery or Gynæcology, in Venereal ease, and in Ophthalmology. Child welfare is also lertaken systematically by officers of the Royal ny Medical Corps.

At the same time instruction in administration is tinuous. The Royal Army Medical Corps is entially organised for war, and one of the lessons of Great War was that trained administrators must st to enable the fullest benefit to be obtained from fessional talent. Many appointments carrying ministrative responsibility are open to those officers display capacity for this duty. All officers must prepared to undertake command and to have a wledge of Army administration, especially in war. ually important is the technical training of the n-commissioned Officers and men of the Corps in h "trades" as Trained Nurse, Nursing Orderly, sseur, Radiographer, Operating Room Assistant, boratory Assistant, Hospital Cook, Dispenser, &c. s training is carried out by the Officers and Nursing ers, and opens a large field for those who have lity in lecturing and teaching as well as the power nfluencing men.

Promotion.

Promotion takes place automatically to Captain after 3½ years, and to Major after 12 years' service, provided the officer is qualified and recommended for promotion. Promotion to the higher ranks is by selection from those senior in the rank below, but special promotion by brevet or otherwise is open to officers of the Royal Army Medical Corps.

Additional Pay and Charge Pay for R.A.M.C. Officers.

(1) Officer not above the rank of lieutenant-colonel, while acting as specialist in a post considered by Our Army Council to merit the grant of additional pay, according to subjects or groups of subjects as under.

Operative Surgery, advanced; Medicine; Ophthalmology; Gynæcology and Midwifery; Dermatology, and Venereal Disease. Otology, Laryngology, and Rhinology; Radiology; Anæsthetics; Mental Diseases; Hygiene; Pathology; subjects other than above, at the discretion of Our Army Council, 5*s.* daily.

(2) (*a*) Officer in charge of a hospital.—If the number of equipped beds, as certified by the Deputy Director of Medical Services, exceeds—

50 beds ..	2*s.* 6*d.* daily.	300 beds ..	7*s.* 6*d.* daily.
150 „ ..	5*s.* 0*d.* „	500 „ ..	10*s.* 0*d.* „

Officer in charge of a medical or surgical division of a general hospital with not less than 300 beds—half the above rates.

	Daily. *s.*	*d.*
(*b*) Senior medical officer, Royal Arsenal, not exceeding	10	0
(*c*) Officer in command of the depôt, Royal Army Medical Corps	5	0
(*d*) The senior officer of the Army Medical Services with an army in the field: A rate to be fixed by the Army Council according to the magnitude of the charge.		
(*e*) The officer, if under the substantive rank of colonel, holding the appointment of senior medical officer in a command abroad, or of assistant director of medical services, if the number of soldiers is 1500 or upwards	5	0
(*f*) Adjutant R.A.M.C. Depôt	5	0
(*g*) Adjutant R.A.M.C. (Territorial Army)	2	6

* Pay Warrant rates as amended by A.O. 196/26 less 6 per cent. from July 1st, 1927, vide A.O. of 1927. The Pay rrant rates are subject to revision to an extent not exceeding 20 per cent. according to variation in the cost of living. The t revision takes place from July 1st, 1930.

† Rates of allowances vary from time to time and issues are subject to conditions laid down in the Allowance Regulations.

THE ARMY DENTAL CORPS.

The Corps is administered by the Director-General, Army Medical Services. It is a joint service for the Army and Royal Air Force, and personnel is required to serve under either force and be interchangeable. Officers and other ranks posted for duty with the Royal Air Force will perform their duties under the Regulations of the Royal Air Force for the employment of dental personnel, but the conditions in the following tables apply equally in either force. Promotion is carried out on one general list. Regulations

for admission to the Army Dental Corps should be obtained from the Under-Secretary of State, War Office, and carefully studied.

Retirement and Retired Pay.

The following are the rates of pension and retired pay :—

1. Retired pay will consist of two parts : (*a*) a service element based on the officer's total service ; (*b*) a rank element for the rank from which the officer retires. An officer with less than 20 complete years' service will not be eligible for retired pay.

2. The scale will be as follows, subject to the reduction of 6 per cent. referred to below :—

(*a*) Service element.—£15 a year for each completed year of service as a medical officer.

(*b*) Rank element.—

Rank from which retired.	After completing 1 year's service in the rank.	After completing each additional year's service.	Maximum rank element.
	£	£	£
Major	12	12	120
Lieutenant - Colonel	150	30	240
Colonel	290	50	390
Major-General ..	440	50	540
Lieutenant - General	590	50	690

The retired pay of an officer retiring with less than one complete year's service in the rank from which he retires will be assessed as though he had retired from the rank below.

Maximum rates of retired pay (*a*) and (*b*) together :—

	£		£
Captain and Subaltern ..	300	Colonel	800
Major	450	Major-General ..	1000
Lieutenant-Colonel ..	600	Lieutenant-General	1200

The above rates are those laid down in the Pay Warrant. They have been reduced by 6 per cent. as from July 1st, 1927.

3. Officers with seven and less than 20 years' service as medical officers may be permitted to retire with a gratuity in accordance with the following scale :—

After 7 years' service as a medical officer .. £1000
" 3 " " " in the rank of Major £2800
" 6 years' service as a medical officer in the rank of Major £3500

OFFICERS : *Appointment and Promotion.*

1. Commissions as Lieutenants in the Army Dental Corps may be given to persons duly qualified under regulations approved by the Army Council.

2. An officer shall be eligible for promotion to the rank of Captain on completion of three and a half years' service and to the rank of Major on completion of 12 years' service in the Corps, provided he has previously qualified in such manner as may be prescribed by the Army Council.

3. Promotion to the rank of Lieutenant-Colonel and Colonel to fill the establishments laid down from time to time for those ranks shall be made by selection of the Army Council, provided the officer has previously qualified for promotion to those ranks in such manner as may be prescribed by the Army Council.

4. Appointments are in the rank of Lieutenant, except in cases where service of three and a half years or more has been given as a temporary dental officer, when the rank of Captain will be given. Service as a temporary dental officer will count towards the three and a half years for promotion to captain, and the 12 years for promotion to Major.

Pay.

The following are the rates for officers of the Army Dental Corps :—

	Per diem. £	s.	d.
Lieutenant	0	18	10
Captain	1	3	6
Captain { after 8 years' total service	1	6	4
Captain { " 10 " " "	1	8	2
Major	1	12	10
Major, after 15 years' total service	1	17	8
" " 18 " " "	2	0	0
" " 20 " " "	2	4	8
Lieutenant-Colonel	2	11	8
Lieutenant-Colonel after 3 years' service as such	2	16	4
Colonel	3	3	6

These rates are 6 per cent. below those shown in the Pay Warrant, 1926, as amended by Army Order 196/26. The latter are subject to revision to an extent not exceeding 20 per cent., according to variation in the cost of living. The next revision takes place on July 1st, 1930.

Charge Pay.

The officer in charge of the Dental Laboratories, Aldershot receives charge pay at the rate of 5*s.* a day if holding the rank of Captain, or 2*s.* 6*d.* a day if holding the rank of Major.

Allowances.

The allowances for officers of the Army Dental Corps are at the same rates as for officers of the Royal Army Medical Corps.

Retirement and Retired Pay or Gratuity.

(1) The rates of retired pay will be the same as for officers of the Royal Army Medical Corps.

(2) Voluntary retirement on retired pay will not be allowed until after twenty years' service.

(3) Earlier retirement on gratuity may be allowed :—

After 8½ years' service as a Dental Officer, gratuity of £1000.
" 15 " " " £2000.
" 18 " " " £3000.

(4) Retirement will be compulsory at the age of 55 years except in the case of a brevet-colonel, who will be retired at the age of 57 years.

(5) A lieutenant who has not qualified for promotion shall be called upon to resign on completion of three and a half years' service, and a captain who has not qualified for promotion shall be retired on gratuity on completion of twelve years' service.

The aim of the Corps is the prevention of wastage of man power on account of dental disease or dental deficiency, and, to enable this to be carried out, every recruit is inspected by a dental officer immediately after joining and all necessary treatment carried out. The soldier is re-inspected at least once a year and his dental efficiency maintained at the best standard possible. As recruits are not now enlisted unless they have sufficient natural teeth to enable them to masticate efficiently, it is hoped that the conservative nature of the treatment they will receive will reduce considerably the percentage of artificial dentures required.

INDIAN MEDICAL SERVICE.

THE entry of European medical candidates into the Indian Medical Service practically ceased with the last open competitive examination held in 1915, and it is an open secret that recruitment for the Service had for many years previous not been brisk, with the result that at the present time the Service is weak officered in its higher ranks and notably deficient in the ranks of those who will be called to succeed them. Among the senior and retired officers are many whose work in medicine and the allied sciences has become a household word, for a generation ago the conditions of service were such as to attract men of the greatest promise in the medical schools who were rarely disappointed in a career which, without producing wealth, gave unlimited opportunity for the display of talent in research and administration unfettered by irksome restriction. We may suppose, and it is the view of many senior officers in the Service, that the period of depression is now passing and that the prospect is again bright for those who are fitted in physique and disposition for a medical career in India. Last year's offer of permanent commissions on specially favourable terms to a small number of medical men of European descent who were free to serve forthwith to India met with the desired response and 20 such commissions were granted.

But the new outlook involves frank acceptance of the Indian reform scheme, the essential of which is increasing participation of Indian-born subjects in the government of the country, although, so long as Europeans are employed in the various departments of the Indian Civil Service, nothing is more certain than that there will and must remain European doctors to attend them. Entrants must also be prepared to face the fact that more time will elapse before they can hope to get into civil employ and

t opportunities for private medical practice are what they were. On the other hand, it is reasonably tain that the social effect of Indianisation will not ss hardly on the medical service for the reason that ropean doctors will be chiefly requisitioned in tions with considerable European communities. these communities the equipment and organisation ospitals has been steadily improving and men with fessional ambition will find positions which will isfy their aspirations. On the military side the tion hospital system has rendered the position of dical officers more independent by making team- k possible and permitting of specialisation in ious departments of medicine and surgery. Lastly, se who join now will have unequalled prospect of rancement in a Service which has been so depleted 10 or 15 years or more, and the new terms of vice announced by the Secretary of State for India year assure conditions of pay, pension, and ough much superior to those recently offered.

The New Provisional Regulations.

ompetitive examination remains suspended for present and admission to the Service is on tten application to the India Office. As sound ily health is a first essential candidates may, if y wish it, undergo a preliminary examination by fedical Board which meets weekly at the India ce.

andidates must be under 32 years of age at the time application and possess qualifications registrable Great Britain. Up to the present time officers have n employed both in civil and military departments have been interchangeable between the two. At beginning of his career an officer was employed the military side, which has medical charge of the ian Army. If he remained in military employ he l a post on the staff of a station hospital, or a cialist post, or a post on the administrative staff he army, promotion being on a time-scale up to the k of lieutenant-colonel and by selection to the ranks olonel and major-general. He could, however, if chose, apply, after two years' Indian military ice, to be registered as a candidate for transfer to civil side, from which appointments are made to l surgeoncies, established at the principal civil tres to provide for the medical needs of civil ials and for general medical administrative pur- es and to the specialist services (for example, lic health, bacteriological and research depart- nts, and the professorships at the medical schools). h transfers normally took place after about n years' service in military employment. view, however, of the recommendations of the Commission only military employment can be ranteed to officers entering at the present time, ough they will be eligible for such civil employment may become available as a result of the Lee mission report. Executive medical officers in h civil and military employment may attend sons unconnected with Government service vided their duty admits of it. On the military , however, the opportunities for private practice not great. Service during the war as a medical ombatant officer, or in a position usually filled by officer, counts towards promotion and pension so as the rights of officers who have entered by petition are not interfered with.

Rates of Pay.

he monthly rates of pay for European officers in Service are as tabulated below. The rupee, ay be remembered, is to be stabilised at 1*s.* 6*d.*, ough the instruction has not yet been made tive in India.

nitial rates of pay are based on the assumption that majority of newly appointed officers will be nelors. An officer, when junior, is liable to more uent changes of station than later on in his ice, and he may therefore be put to considerable nse for transfers if he has a family. Officers are married before joining may find difficulty in living within their pay during the first few years of their service. Officers in military employment, when in command or second-in-command of the larger station hospitals, receive special allowances. On the civil side there are public health, bacteriological, research, and professorial appointments carrying special enhanced rates. Special rates of pay are attached to administrative appointments. Officers on appointment receive an outfit allowance of £50.

Rank and service in rank.	Basic pay.	Overseas pay. If drawn in sterling.	Overseas pay. If drawn in rupees.	Year of total service.
	Rs.	£	Rs.	
Lieut.	500	—	150	First
		—	150	Second
		—	150	Third
Captain :—

2. With more than three and less than six years' service as Major	1100	—	—	—
3. With more than six years' service as Major.	1250	30	300	Thirteenth and over.
Lieut.-Colonel :—				
1. Until completion of 23 years' total service	1500	—	—	—
2. During twenty-fourth and twenty-fifth years' total service	1600	—	—	—
3. After completion of 25 years' total service	1700	—	—	—
4. When selected for increased pay ..	1850	—	—	—

Note.—Until the completion of 23 years' total service basic pay is regulated according to rank and service in rank (column 1) which, owing to the system of accelerated promotion, may be in advance of the time-scale of promotion. Overseas pay is regulated solely with reference to length of total service (column 5). In addition to grades there are a number of appointments as colonels on Rs.2200 to Rs.2500, according to the appointment held, and as major-general on Rs.2750. The appointment of Director of Medical Services in India, carrying pay at Rs.3200 per mensem, may also be held by an officer of the Indian Medical Service.

Pensions and Allowances.

The rates of pensions are as shown in the table below.

Service.	Rates per annum.	Service.	Rates per annum.
After 17 years ..	£400	After 23 years ..	£620
,, 18 ,, ..	430	,, 24 ,, ..	660
,, 19 ,, ..	460	,, 25 ,, ..	700
,, 20 ,, ..	500	,, 26 ,, ..	750
,, 21 ,, ..	540	,, 27 ,, ..	800
,, 22 ,, ..	580		

Note.—The above rates are subject to revision, upwards or downwards, to an extent not exceeding 20 per cent. in all, on account of a rise or fall in the cost of living, as compared with the year 1919. A deduction of 4½ per cent. on this account has already been made. Nevertheless the full pension of a lieutenant-colonel cannot be cut below the maximum of £700 under the old rules in the case of officers who entered the service before July 1st, 1920.

There are additional pensions not subject to the above reduction ranging from £125 to £350 per annum for officers who have held high administrative appointments as colonels or major-generals.

Officers on appointment are, when possible, provided with passage to India by transport. When such

accommodation is not available passage is provided by private steamer, or passage allowance granted if preferred. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be given free passage to India. Officers are granted a certain number of return pasages home at Government expense during their career. There are special allowances for officers whilst on study leave.

Further particulars can be obtained on application to the Secretary, Military Department, India Office, Whitehall, London, S.W. 1. Letters should be marked "Recruitment for I.M.S."

ROYAL AIR FORCE MEDICAL SERVICE.

THE Air Council attach great importance to attracting into the Service the best type of medical man, since on the capacity of the Medical Service depends in a peculiar degree the safety and efficiency of the Air Force. The duties of a medical officer in the Air Force include not only the prevention and treatment of those ordinary diseases to which the personnel of any fighting service are liable, but the special study of the mental and physical stresses imposed on the airman in diverse circumstances and climates—a new branch of medicine which still provides considerable scope for research.

As promotion to the higher ranks of the Service is by selection from officers who are eligible by reason of length of service, and as a certain proportion of the higher ranks will be reserved for purely scientific as opposed to administrative appointments, it will be seen that there are excellent prospects for the young medical officer who exhibits ability and energy in scientific research, as well as for those who develop talents for administration.

The work to be done, therefore, has a high professional interest which, combined with good rates of pay and allowances, offers a career for medical men which should prove both attractive and interesting. The life is one which is certain to appeal to the man of wide outlook who desires opportunities for travel, sport, and games, and can find interest and enjoyment in aviation.

His duties will, as a matter of course, give him flying experience as a passenger, which is necessary for the proper study of the medical problems of aviation and for gaining first-hand knowledge of the conditions under which his comrades serve.

The establishment will consist partly of permanent and partly of short-service officers.

An officer will on first entry be granted a sho service commission for a period of three years on t active list (which may be extended to five years the discretion of the Air Council if the officer wishes on the recommendation of the Director Medical Services) and of four years in the Reserve Air Force Officers. Selections for permanent co missions will be made from officers holding sho service commissions, and those who are n selected will be transferred to the Reserve at t expiration of their period of service on the acti list.

For those entrants who desire it the prospect obtaining a permanent commission is approximat an even one. Experience has so far shown that t officers selected have included the great majority those desirous of, and suitable for, retention in t Service; owing to the fact that the short-servi commission with its gratuity after three or five ye is in itself an attraction to many entrants who des to enlarge their experience and outlook from t point of view of subsequently entering private practi or who, on entry, have not made up their minds the adoption of a permanent career in the Service a subsequently find that they would prefer to retu to civil life.

For certain purposes medical officers may allowed to count as service their time spent resident appointments in civil hospitals under certa well-defined and generous conditions.

Officers who have been selected for permane commissions may be permitted to attend for a peri not exceeding nine months a post-graduate cou in general medicine and surgery, tropical and prev tive medicine, and other special subjects. Su permission may be granted at any time when t exigencies of the Service permit during the fi 16 years of service, and when attending these cour officers will receive full pay and allowances.

New entrants into the Royal Air Force Medi Service will be commissioned as Flying Offic (Medical) and will be eligible for promotion to t rank of Flight Lieutenant (Medical) after two ye service. Officers selected for permanent commissio will normally be promoted to the rank of Squadr Leader after ten years' total service. Accelerat promotion may be granted in a limited number cases to officers who show exceptional ability af the completion of eight years' service. Promot within establishment to the rank of Wing Comman will be by selection at any period after 16 years' to service, and that of Group Captain by selection at a period after 22 years' service.

* Except for periods of service under Indian administration. For such periods officers receive pay and allowances at r and subject to conditions authorised from time to time by the Government of India.

† These allowances are issued only when accommodation, fuel and light, rations, and personal attendance are not avail in kind. Normally, provision in kind is available for junior officers. "Married" rates of allowances are payable only to mar officers who have reached the age of 30 or the rank of Squadron Leader. A colonial allowance is granted in certain comma abroad. The rates and general scheme of allowances are liable to revision as circumstances may require.

There will be no competitive examination on entry; ndidates must be under 28 years of age, be British bjects, the sons of British subjects, and of pure ropean descent, be nominated by the dean of a ognised medical school or teaching hospital, and ll be interviewed personally by the Director of dical Services, Royal Air Force, before acceptance. ch candidate must produce :—

. Birth certificate. 2. Medical registration certificate. A declaration containing the following information: Age and place of birth. (*b*) That he is a British subject, son of British subjects, and of pure European descent. That he is ready to engage for general service at home or oad as required. (*d*) The qualifications he is possessed and what medical or other appointments he has held any). (*e*) That he is willing to fly as a passenger whenever led upon to do so.

Each candidate will be required, before acceptance, pass a medical examination to ensure that he ours under no constitutional or mental disease or eases or weakness, nor any imperfection or disability ich may interfere with the efficient discharge of e duties of a medical officer in any climate, in ace or war.

On appointment entrants will undergo an initial rse of eight weeks, during which they will be given truction in the special medical aspects of aviation, e organisation and administration of the Royal Air rce, and the general and special duties to be rformed by officers in the Medical Branch.

In order to avoid the necessity for further examina- ns the position of entrants in order of seniority the Air Force List will be determined at the end the initial course by a system of marking and orts on the actual work done during their truction.

Uniform and Equipment.

Medical officers are required to provide themselves th the uniform, service dress, and mess dress of their nk and with the distinguishing badges of the Royal r Force Medical Branch. The provision of full dress entirely optional at present. An allowance of £50 wards the cost of uniform is made on joining to ndidates who have not had previous commissioned vice in H.M. Forces.

Emoluments.

The emoluments of medical officers of the Royal Air rce are given in outline above. The standard rates pay and retired pay were drawn up on the basis the high cost of living in 1919, and 20 per cent. of ch of the standard rates is detachable and subject alteration either upwards or downwards as the st of living rises or falls. Under this provision e current rates now in force represent a reduction approximately 6 per cent. on the standard rates. e next revision will take effect from July 1st, 1930, d subsequent revisions will be made at intervals three years.

RETIRED PAY.

The minimum period of service qualifying for irement on retired pay is 20 years. Standard rates retired pay are as follows :—

Air Officers.

Air Vice-Marshal .. .. £790 to £1010 per annum.
Air Commodore .. .. £650 ,, £950 ,, ..

The maximum standard rates of retired pay and e compulsory retiring ages for the several ranks e :—

Rank.	Yearly rate of retired pay.	Compulsory retiring age.
	£	
Air Vice-Marshal ..	1010	60
Air Commodore ..	950	57
Group Captain	900	55
Wing Commander ..	600	51
Squadron Leader ..	500	48

Retired Pay of Officers below Air Rank.

Age on retirement.	Standard yearly rate of retired pay.	Years of service.	Addition for each extra year of service.*	Deduction for each deficient year of service.*
	£		£	£

* Limited to five years.

Gratuities.—A permanent officer allowed to retire before having qualified for retired pay may be granted a gratuity provided he has not less than ten years' commissioned service, namely :—

£1500 if he has 10 but less than 15 years' commissioned service.
£2500 ,, 15 or more than 15 ,, ,, ,,

Short-service officers will be eligible on passing to the Reserve for gratuities on the following scale: £100 for each of the first two complete years of service, £150 for each of the third and fourth complete years, and £200 for the fifth complete year; that is :—

For three years' service on the active list .. £350
For five ,, ,, ,, .. £700

These gratuities will not be payable to officers granted permanent commissions, but their service on a short-service commission will count towards retired pay.

COLONIAL MEDICAL SERVICE.

IN the self-governing dominions, Canada, Australia, New Zealand, the Union of South Africa, and Newfoundland, and territories under their control, such as Papua and the Cook Islands and in the self-governing colony of Southern Rhodesia, medical appointments are made concerning which information can be obtained from the High Commissioners or Agents-General in London; appointments in Egypt and the Soudan are regulated from the Foreign Office; in North Borneo application should be made to the British North Borneo Company, 37, Threadneedle-street, E.C., for appointments; and those in Sarawak are in the hands of H.H. the Rajah. Much valuable information will be found in the "Professional Handbook," Part II., issued by the Oversea Settlement Office, 3 and 4, Clement's Inn, Strand, London, W.C. 2, price 9*d*.

As a general rule, each Colony or Protectorate has its own public service distinct from that of every other; and it is usually only the higher officers who are transferred by the Secretary of State from one Colony to another. There are three exceptions to this rule: (*a*) The West African Medical Staff, which serves Nigeria, the Gold Coast, Sierra Leone, and the Gambia, is one service. (*b*) The East African Medical Service, which serves Kenya, Uganda, Zanzibar, Nyasaland, Somaliland, and the Tanganyika Territory is one service. (*c*) In practice the medical services of the Straits Settlements and the Malay States may be regarded as one, as the officers may be and frequently are transferred from the Colony to the States or vice versa.

The Colonies, Protectorates, and Mandated Territories to which medical officers are appointed by the Secretary of State for the Colonies are (*a*) the West African—viz., Nigeria, the Gold Coast, Sierra Leone, and the Gambia; (*b*) the East African—viz., the Kenya Colony and Protectorate, the Uganda, Nyasa-

land, Somaliland, and Zanzibar Protectorates, the Tanganyika Territory, and Northern Rhodesia; (*c*) the Eastern—viz., Ceylon, the Straits Settlements and Malay States, Hong-Kong, Mauritius, and Seychelles; (*d*) the West Indian—viz., British Guiana, Jamaica, Trinidad, the Windward Islands, the Leeward Islands, Barbados, British Honduras, and the Bahamas; (*e*) Fiji and the Western Pacific, Cyprus, Gibraltar, St. Helena, Bermuda, and the Falkland Islands; and (*f*) Palestine.

In Ceylon, Mauritius, Jamaica, Barbados, the Bahamas, and Bermuda vacancies are practically always filled locally by the appointment of qualified native candidates, or—in the case of some of the higher posts—by transfer from other Colonies. In the Bechuanaland Protectorate, Basutoland, and Swaziland appointments are usually filled locally. Appointments in Malta are all filled locally. Vacancies occur most regularly and frequently in the West African Medical Staff, the East African Medical Service, and the Straits Settlements and Malay States.

All applicants for medical appointments in the gift of the Secretary of State for the Colonies should be between the ages of 23 and 35,[1] and must be doubly qualified; preference will be given to those who have held hospital appointments as house physicians and house surgeons; testimonials to character and professional competence will be required, and every officer before being definitely appointed will be medically examined by one of the consulting physicians of the Colonial Office: Sir William Prout, C.M.G., O.B.E., and Dr. A. E. Horn, C.M.G., 79, Harley-street, London, W. 1; Major-General J. J. Gerrard, C.B., C.M.G., the Royal Hospital, Kilmainham, Dublin; Dr. Foster Coates, 9, Shaftesbury-square, Belfast; and Lieut.-Colonel Glen Liston, C.I.E., I.M.S., 33, Comely Bank, Edinburgh; Applications for such appointments must be addressed to the Private Secretary (Appointments), Colonial Office, 38, Old Queen-street, S.W. 1.

EAST AFRICAN MEDICAL SERVICE.

The Medical staffs of the Kenya Colony and Protectorate, the Uganda, Nyasaland, Somaliland, and Zanzibar Protectorates, and the Tanganyika Territory form one service, the members of which are liable to be posted to any of the Dependencies as the exigencies of the service may require. The preferences of individual officers are, however, taken into consideration as far as possible.

Selected candidates are appointed as medical officers on probation in the first instance for two years, at the end of which period their appointments are made permanent if their service has been satisfactory. Unless the Secretary of State directs to the contrary, they are required to attend a course of instruction at the London or Liverpool School of Tropical Medicine or the University of Edinburgh before taking up their appointments. If such a course is not taken before proceeding to East Africa, they are required to take it during their first leave of absence. Medical officers (but not sanitation officers) are permitted to take private practice at some stations on the understanding that they give precedence to their official duties. It must be understood that additions to their income from this source are not likely to be substantial, and that the privilege is liable to withdrawal at any time.

Officers are provided with quarters free of rent or the Government may provide temporary accommodation, or an allowance in lieu of quarters calculated at 15 per cent. of the initial salary of an officer's appointment may be paid. The salary of a medical or sanitation officer is £600 per annum, rising by annual increments of £30 to £840, and thence by increments of £40 to £920, subject to an efficiency bar at £840. Senior medical officers and seni sanitation officers are paid on the scale £1000 b annual increments of £50 to £1100. Officers wh possess the Diploma in Public Health on entering, who acquire it while in the Service, receive two speci increments in the scale.

Officers of the East African Medical Service a permitted to retire with gratuity, if they wish, inste of waiting to retire on pension as follows: (*a*) Aft nine years' service, of which at least six must ha been spent in East Africa, £1000; (*b*) after 12 yea service, of which at least eight must have been spe in East Africa, £1250. If an officer elects to reti with gratuity he thereby forgoes all claim t pension.

The grades and salaries (apart from ordina medical and sanitation officers) in the medical depar ments are as follows:—

Kenya.—Director of Medical and Sanitary Service £1500; Deputy Director of Medical Service, £1200: Deput Director of Sanitary Service, £1200; Deputy Director Laboratory Service, £1200.

Uganda.—As Kenya.

Tanganyika Territory.—As Kenya.

Nyasaland.—Director of Medical and Sanitary Service £1300.

Zanzibar.—Director of Medical and Sanitary Service £1400; Deputy Director of Sanitary Service, £1200.

Somaliland.—Principal Medical Officer, £1000–£50–£110

Sanitation officers are selected from the ranks medical officers as occasion arises.

ASIA.

Straits Settlements and Federated Malay States.— European medical officers are appointed on t following scale of salaries: $500 per mensem, rising $550 per mensem during three years' probatio then, if they are placed on the pensionable establis ment, rising to $575 per mensem, and thence b annual increments of $25 per mensem to $800 p mensem, with a strict efficiency bar at $600 p mensem. This scale of salaries has been fixed on t supposition that medical officers join the service about the age of 27. Officers possessing the D.P.H receive an additional allowance of $100 per mense

Above the concluding figure of $800 per mense there are certain higher appointments, as follow Principal Civil Medical Officer, Straits Settlements, ar Principal Medical Officer, Federated Malay State $1200 per mensem; Director, Institute for Medic Research, Federated Malay States, Chief Healt Officer, Federated Malay States, and Princip Medical College, Straits Settlements, $1100 p mensem; 12 posts at $1050 per mensem; and posts at $850 per mensem, rising annually by $30 $1000 per mensem.

The following temporary allowances are at prese paid to all officers recruited from Europe in t Government Services of the Straits Settlements ar Federated Malay States: unmarried officers, 10 p cent. of salary; married officers, 20 per cent. salary. Private practice by Government medic officers is not allowed. They may, however, do, ar receive fees for, consultative work, if approved by t Government. Information about general conditio in Malaya is obtainable from the Malay Stat Information Agency, 88, Cannon-street, E.C. 4.

British Guiana.—There are the following posts in medical service of the Colony: one surgeon-eral, £1000–£1200 per annum, with consulting ctice; one medical officer of health, £900; one teriologist, £450–£700 (increment £25), with £50 wance in lieu of fees; 34 medical officers at 0–£25–£700. Some of the senior posts also carry y allowances (varying from £50 to £300 per annum) quarters. All the junior appointments in which rate practice is not allowed carry duty allowances. vate practice is allowed in certain cases.

Trinidad and Tobago.—In Trinidad and Tobago re are over 40 appointments. On appointment rernment medical officers, who are provided with unfurnished quarters, receive salary at the rate 400 per annum with annual increments of £25 ruing from the date of first appointment as super-nerary medical officers, until reaching the maximum 600. An officer appointed to a district receives, addition to his salary, a travelling allowance ying from £100 per annum in a normal district to) per annum, and is allowed private practice, value of which is estimated at from £50 to £800 annum. Officers employed in institution work ive allowances in lieu of private practice varying n £50 (and furnished quarters) to £300. Medical ers having completed 10 years' resident service are sionable at the age of 55.

Windward Islands (Grenada, St. Lucia, St. Vincent). re are over 25 appointments. The chief ical and health officer, Grenada, receives £600–). The chief medical officer, St. Lucia, receives)–£700 plus forage and subsistence allowances; post is pensionable, but private practice is not wed except as a consultant. Most of the remain-appointments are district appointments with right to private practice attached; the salaries by Government vary from £400–£500, and with wances in certain cases. The Governor has power to transfer a medical officer from one id to another. Appointments are pensionable.

Leeward Islands (Antigua, St. Christopher and is, Dominica, Montserrat, Virgin Islands).—There 20 appointments with salaries varying from to £400 of the same nature as in the Windward nds and pensionable. An officer when first out is not appointed to a particular island to the service of the Leeward Islands, with a ry varying from £312 to £400, according to station, the Governor decides as to the district which is to llotted to him. He is liable to be transferred at Governor's discretion to any medical district in Leeward Islands, and in certain districts may be ired to perform magisterial duties. The medical ers receive fees for successful vaccinations, post-tem examinations, evidence at courts of justice, ificates of lunacy, and, in the larger islands, for al certificates. They are also, as a rule, allowed ate practice. The chief medical officer, St. Kitts, ves £700–£25–£750 without private practice.

Antigua.—Medical Superintendent, Holburton pital, and Chief Medical Officer is in receipt of ary of £600, plus £50 as Chief Medical Officer and elling allowance of £25. Fees average £100.

British Honduras.—There are seven medical appoint-ts (besides the post of principal medical officer), salary of $2430 per annum with increments $120 to $3150. Unless they already possess ploma of public health, medical officers are e to be required, before they join the colony, ndergo a course of instruction at a laboratory of ic health or analogous institution. The salary he Principal Medical Officer is $4008, with one ment of $120 to $4128. The value of the dollar proximately the same as that of the United States.

OTHER OVERSEAS APPOINTMENTS.

Fiji.—The Chief Medical Officer receives £1000–£50–£1100; the Medical Superintendent, Colonial War Memorial Hospital, £800–£25–£1000; the Medical Superintendent, Makogai Leper Asylum, £700–£50–£950; the Medical Officer of Health, Suva, £750–£25–£900. There are 12 District Medical Officers who receive £500–£25–£725. All the above, except the Medical Officer of Health, are entitled to free partly furnished quarters or an allowance in lieu thereof. District Medical Officers are allowed private practice on the understanding that their official duties are not neglected. The Chief Medical Officer, the Medical Superintendent, Colonial War Memorial Hospital, and the Medical Officer of Health are allowed consulting practice only. In five districts the Medical Officer is also District Commissioner and receives an additional allowance of from £175 where there is some private practice to £275 where there is none. In the other districts the value of private practice is estimated at from £200 to £600 a year.

Western Pacific High Commission.—The staff in the British Solomon Islands Protectorate consists of a Senior Medical Officer (£650–£750), one District Medical Officer (£550–£650), and one Travelling Medical Officer (£550–£650). Partly-furnished quarters are provided and a local allowance of £50 per annum is paid in respect of resident service in the Protectorate.

In the Gilbert and Ellice Islands Colony there is a Senior Medical Officer (£650–£750) and one Medical Officer (£500–£25–£600). Partly furnished quarters are provided. There is hardly any private practice in the British Solomon Islands Protectorate or the Gilbert and Ellice Islands Colony.

Cyprus.—There is a chief medical officer paid at the rate of £750, rising by annual increments of £25 to £900, and three district medical officers paid at the rate of £500 a year, rising by annual increments of £20 to £600 a year, all enjoying private practice (except the chief medical officer, who is allowed consulting practice only) and receiving 2*s.* per diem forage allowance. There is also a medical officer of health on £600, rising by £20 increments to £720 without private practice; these are the only medical appointments open to English candidates.

Gibraltar.—There is a surgeon of the Colonial Hospital receiving £750, and private practice. There are also two assistant surgeons with a salary of £720 per annum, who are allowed private consulting practice only. Free quarters, unfurnished, are provided for all three officers.

St. Helena.—The colonial surgeon at present receives £550 per annum, fees estimated at about £27 a year, and £30 horse allowance. The assistant colonial surgeon at present receives £500 a year and £30 horse allowance. Private practice is allowed, and such practice, together with the duties of non-Government appointments, is divided between the colonial surgeon and the assistant colonial surgeon in a proportion approved by the Governor. The value of private practice and appointments is estimated at about £536 a year.

Falkland Islands.—There are two appointments. The colonial surgeon is paid at the rate of £600 per annum, with free furnished quarters. The assistant colonial surgeon is paid at the rate of £500 per annum, with an allowance of £50 per annum in lieu of quarters. Private practice is shared between the colonial surgeon and the assistant colonial surgeon. The office of colonial surgeon is pensionable.

Palestine.[2]—The grades and salaries of superior appointments in the Department of Health are: Director, £E.1200, plus £E.200 expatriation allowance. Deputy Director, £E.900–50–1100, plus £E.150 expatriation allowance. Assistant Director (Laboratories), Specialist Surgeon,[3] and five Senior Medical

[2] £1 Egyptian (of 100 piastres) is equivalent to £1 0*s.* 6*d.* sterling, but a new currency is being introduced.

[3] A certain amount of private practice is allowed.

Officers, £E.750–25–950, plus £E.100 expatriation allowance. One Assistant Senior Medical Officer and Government Analyst £E.550–25–750, plus £E.100 expatriation allowance. The remainder of the staff is recruited locally.

LEAVE AND PENSIONS.
